	Foreword	Chapter:	Page: vi

FOREWORD

Section 59 of the Civil Aviation Act of Bhutan 2016 empowers the Head of Authority, in this case the Director of Civil Aviation Authority of Bhutan (BCAA), to make Rules and Regulations concerning the use of the airspace, air navigation facilities and services. Accordingly, BCAR-10 Volume I (Radio navigation aids) containing provision incorporating the standard and recommended practices of ICAO Annex 10 Volume I has been developed.

BCAR-10 or BCAR – Aeronautical Telecommunication, which are to be used interchangeably and construed to refer to this document, is hereby published in accordance with section 56 of the act.

During the transposing of the standard and recommended practices of ICAO Annex 10 Volume I to this BCAR, some provisions that are not applicable or currently irrelevant have been left out and marked as “Reserved”. These provisions will be incorporated as and when appropriate.

Any difference existing in this BCAR and the related ICAO Standards and Recommended Practices and any amendments thereto will be notified to the ICAO and the same shall be published in the Aeronautical Information Publication (AIP).

BCAR-10 Volume I hereby supersedes the BCAR-Aeronautical Telecommunication Volume I that was published on October 1, 2010.

This BCAR is a controlled document and the provisions contained herein are subject to change through amendments.

Director
Bhutan Civil Aviation Authority

CHAPTER 1. DEFINITIONS

Note 1- All references to “Radio Regulations” are to the Radio Regulations published by the International Telecommunication Union (ITU). Radio Regulations are amended from time to time by the decisions embodied in the Final Acts of World Radio communication Conferences held normally every two to three years. Further information on the ITU processes as they relate to aeronautical radio system frequency use is contained in the Handbook on Radio Frequency Spectrum Requirements for Civil Aviation including statement of approved ICAO policies (ICAO Doc 9718).

Note 2 - BCAR-10, Volume I include Standards and Recommended Practices for certain forms of equipment for air navigation aids.

Note 3.— The terminology used in this document to refer to instrument approach operations is based on a previous version of the ICAO Annex 6 classification of instrument approach and landing operations. It can be mapped to the ICAO Annex 6 definitions as follows:

Performance requirements in support of instrument approach operations		
Annex 10 system performance		Annex 6 method — Approach operation category
Non-precision approach (NPA)		2D-Type A ⁽¹⁾
Approach with vertical guidance (APV)		3D-Type A ⁽²⁾
Precision approach (PA)	Category I, DH equal to or greater than 75 m (250 ft)	3D-Type A ⁽³⁾
	Category I, DH equal to or greater than 60 m (200 ft) and less than 75 m (250 ft)	3D-Type B — CAT I ⁽³⁾
	Category II	3D-Type B — CAT II
	Category III	3D-Type B — CAT III

(1) Without vertical guidance.

(2) With barometric or SBAS vertical guidance.

(3) With ILS, MLS, GBAS or SBAS vertical guidance.

When the following terms are used in this volume, they have the following meanings:

Altitude. The vertical distance of a level, a point or an object considered as a point, measured from mean sea level (MSL).

Area navigation (RNAV). A method of navigation which permits aircraft operation on any desired flight path within the coverage of ground- or space-based navigation aids or within the limits of the capability of self-contained aids, or a combination of these.

Note. — Area navigation includes performance-based navigation as well as other operations that do not meet the definition of performance-based navigation.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Definitions	Chapter: 1	Page:2

Effective acceptance bandwidth. The range of frequencies with respect to the assigned frequency for which reception is assured when all receiver tolerances have been taken into account.

Effective adjacent channel rejection. The rejection that is obtained at the appropriate adjacent channel frequency when all relevant receiver tolerances have been taken into account.

Elevation. The vertical distance of a point or a level, on or affixed to the surface of the earth, measured from mean sea level.

Essential radio navigation service. A radio navigation service whose disruption has a significant impact on operations in the affected airspace or aerodrome.

Fan marker beacon. A type of radio beacon, the emissions of which radiate in a vertical fan-shaped pattern.

Height. The vertical distance of a level, a point or an object considered as a point, measured from a specified datum.

Human Factors principles. Principles which apply to design, certification, training, operations and maintenance and which seek safe interface between the human and other system components by proper consideration to human performance.

Mean power (of a radio transmitter). The average power supplied to the antenna transmission line by a transmitter during an interval of time sufficiently long compared with the lowest frequency encountered in the modulation taken under normal operating conditions.

Note. — A time of 1/10 second during which the mean power is greatest will be selected normally.

Navigation specification. A set of aircraft and flight crew requirements needed to support performance-based navigation operations within a defined airspace. There are two kinds of navigation specifications:

Required navigation performance (RNP) specification. A navigation specification based on area navigation that includes the requirement for performance monitoring and alerting, designated by the prefix RNP, e.g. RNP 4, RNP APCH.

Area navigation (RNAV) specification. A navigation specification based on area navigation that does not include the requirement for performance monitoring and alerting, designated by the prefix RNAV, e.g. RNAV 5, RNAV 1.

Note.1— The Performance-based Navigation (PBN) Manual (ICAO Doc 9613), Volume II, contains detailed guidance on navigation specifications.

Note 2. — The term RNP, previously defined as “a statement of the navigation performance necessary for operation within a defined airspace”, has been removed from this document as the concept of RNP has been overtaken by the concept of PBN. The term RNP in this document is now solely used in the context of navigation specifications that require performance monitoring and alerting, e.g. RNP 4 refers to the aircraft and operating requirements, including a 4 NM lateral performance with on-board performance monitoring and alerting that are detailed in ICAO Doc 9613.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Definitions	Chapter: 1	Page:3

Performance-based navigation (PBN). Area navigation based on performance requirements for aircraft operating along an ATS route, on an instrument approach procedure or in a designated airspace.

Note - Performance requirements are expressed in navigation specifications (RNAV specification, RNP specification) in terms of accuracy, integrity, continuity, availability and functionality needed for the proposed operation in the context of a particular airspace concept.

Pressure-altitude. An atmospheric pressure expressed in terms of altitude which corresponds to that pressure in the Standard Atmosphere.

Protected service volume. A part of the facility coverage where the facility provides a particular service in accordance with relevant SARPs and within which the facility is afforded frequency protection.

Radio navigation service. A service providing guidance information or position data for the efficient and safe operation of aircraft supported by one or more radio navigation aids.

Touchdown. The point where the nominal glide path intercepts the runway.

Note - “Touchdown” as defined above is only a datum and is not necessarily the actual point at which the aircraft will touch the runway.

Z marker beacon. A type of radio beacon, the emissions of which radiate in a vertical cone-shaped pattern.

	Aeronautical telecommunication Volume - I	BCAR-10	
	General provision for radio navigation aids	Chapter: 2	Page: 1

CHAPTER 2. GENERAL PROVISIONS FOR RADIO NAVIGATION AIDS

2.1 Standard radio navigation aids

2.1.1 The standard radio navigation aids shall be:

- a) the global navigation satellite system (GNSS) conforming to the Standards contained in Chapter 3, 3.7;
- b) the VHF omnidirectional radio range (VOR) conforming to the Standards contained in Chapter 3, 3.3;
- c) the non-directional radio beacon (NDB) conforming to the Standards contained in Chapter 3, 3.4;
- d) the distance measuring equipment (DME) conforming to the Standards contained in Chapter 3, 3.5;
and

2.1.2 Differences in radio navigation aids in any respect from the Standards of Chapter 3 shall be published in an Aeronautical Information Publication (AIP).

2.1.3 (Reserved) ILS and MLS

2.1.4 GNSS-specific provisions

2.1.4.1 It shall be permissible to terminate a GNSS satellite service provided by one of its elements (Chapter 3, 3.7.2) on the basis of at least a six-year advance notice by a service provider.

2.1.4.2 GNSS data relevant to GNSS-based operations shall be recorded if approved by BCAA.

Note 1. — These recorded data can support accident and incident investigations. They may also support periodic analysis to verify the GNSS performance parameters detailed in the relevant Standards in this Annex.

Note 2 - Guidance material on the recording of GNSS parameters and on GNSS performance assessment is contained in Attachment D, 11 and 12.

2.1.4.3 Recordings should be retained for a period of at least 14 days. When the recordings are pertinent to accident and incident investigations, they should be retained for longer periods until it is evident that they will no longer be required.

2.1.5 (Reserved) Precision approach radar

2.1.6 When a radio navigation aid is provided to support precision approach and landing, it should be supplemented, as necessary, by a source or sources of guidance information which, when used in conjunction with appropriate procedures, will provide effective guidance to, and efficient coupling (manual or automatic) with, the desired reference path.

Note - DME, GNSS, NDB, VOR and aircraft navigation systems have been used for such purposes.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	General provision for radio navigation aids	Chapter: 2	Page: 2

2.2 Ground and flight testing

2.2.1 Radio navigation aids of the types covered by the specifications in Chapter 3 and available for use by aircraft engaged in national and international air navigation shall be the subject of periodic ground and flight tests.

Note - Guidance on the ground and flight testing of ICAO standard facilities, including the periodicity of the testing, is contained in Attachment C and in the Manual on Testing of Radio Navigation Aids (ICAO Doc 8071).

2.3 Provision of information on the operational status of radio navigation services

2.3.1 Aerodrome control towers and units providing approach control service shall be provided with information on the operational status of radio navigation services essential for approach, landing and take-off at the aerodrome(s) with which they are concerned, on a timely basis consistent with the use of the service(s) involved.

2.4 Power supply for radio navigation aids and communication systems

2.4.1 Radio navigation aids and ground elements of communication systems of the types specified in BCAR 10 shall be provided with suitable power supplies and means to ensure continuity of service consistent with the use of the service(s) involved.

Note. — Guidance material on power supply switch-over is contained in Attachment C, 8.

2.5 Human Factors considerations

2.5.1 Human Factors principles should be observed in the design and certification of radio navigation aids.

Note - Guidance material on Human Factors principles can be found in the Human Factors Training Manual (ICAO Doc 9683) and Circular 249 (Human Factors Digest No. 11 - Human Factors in CNS/ATM Systems).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 1

CHAPTER 3. SPECIFICATIONS FOR RADIO NAVIGATION AIDS

Note. —Specifications concerning the siting and construction of equipment and installations on operational areas aimed at reducing the hazard to aircraft to a minimum are contained in ICAO Annex-14, Chapter 8.

3.1(Reserved) Specification for ILS

3.2 (Reserved) Specification for precision approach radar system

3.3 Specification for VHF omni-directional radio range (VOR)

3.3.1 General

3.3.1.1 The VOR shall be constructed and adjusted so that similar instrumental indications in aircraft represent equal clockwise angular deviations (bearings), degree for degree from magnetic North as measured from the location of the VOR.

3.3.1.2 The VOR shall radiate a radio frequency carrier with which are associated two separate 30 Hz modulations. One of these modulations shall be such that its phase is independent of the azimuth of the point of observation (reference phase). The other modulation (variable phase) shall be such that its phase at the point of observation differs from that of the reference phase by an angle equal to the bearing of the point of observation with respect to the VOR.

3.3.1.3 The reference and variable phase modulations shall be in phase along the reference magnetic meridian through the station.

Note - The reference and variable phase modulations are in phase when the maximum value of the sum of the radio frequency carrier and the sideband energy due to the variable phase modulation occurs at the same time as the highest instantaneous frequency of the reference phase modulation.

3.3.2 Radio frequency

3.3.2.1 The VOR shall operate in the band 111.975 MHz to 117.975 MHz except that frequencies in the band 108 MHz to 111.975 MHz may be used when, in accordance with the provisions of Volume V, Chapter 4, 4.2.1 and 4.2.3.1, the use of such frequencies is acceptable. The highest assignable frequency shall be 117.950 MHz. The channel separation shall be in increments of 50 kHz referred to the highest assignable frequency. In areas where 100 kHz or 200 kHz channel spacing is in general use, the frequency tolerance of the radio frequency carrier shall be plus or minus 0.005 per cent.

3.3.2.2 The frequency tolerance of the radio frequency carrier of all new installations implemented after 23 May 1974 in areas where 50 kHz channel spacing is in use shall be plus or minus 0.002 per cent.

3.3.2.3 In areas where new VOR installations are implemented and are assigned frequencies spaced at 50 kHz from existing VORs in the same area, priority shall be given to ensuring that the frequency tolerance of the radio frequency carrier of the existing VORs is reduced to plus or minus 0.002 per cent.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 2

3.3.3 Polarization and pattern accuracy

3.3.3.1 The emission from the VOR shall be horizontally polarized. The vertically polarized component of the radiation shall be as small as possible.

Note - It is not possible at present to state quantitatively the maximum permissible magnitude of the vertically polarized component of the radiation from the VOR. (Information is provided in the Manual on Testing of Radio Navigation Aids (ICAO Doc 8071) as to flight checks that can be carried out to determine the effects of vertical polarization on the bearing accuracy.)

3.3.3.2 The ground station contribution to the error in the bearing information conveyed by the horizontally polarized radiation from the VOR for all elevation angles between 0 and 40 degrees, measured from the center of the VOR antenna system, shall be within plus or minus 2 degrees.

3.3.4 Coverage

3.3.4.1 The VOR shall provide signals such as to permit satisfactory operation of a typical aircraft installation at the levels and distances required for operational reasons, and up to an elevation angle of 40 degrees.

3.3.4.2 The field strength or power density in space of VOR signals required to permit satisfactory operation of a typical aircraft installation at the minimum service level at the maximum specified service radius should be 90 microvolts per meter or minus 107 dBW/m².

Note - Typical equivalent isotopically radiated powers (EIRPs) to achieve specified ranges are contained in 3.1 of Attachment C. The definition of EIRP is contained in 3.5.1.

3.3.5 Modulations of navigation signals

3.3.5.1 The radio frequency carrier as observed at any point in space shall be amplitude modulated by two signals as follows:

- a) a subcarrier of 9 960 Hz of constant amplitude, frequency modulated at 30 Hz:
 - i. Reserved (For Conventional VOR).
 - ii. for the Doppler VOR, the phase of the 30 Hz component varies with azimuth and is termed the “variable phase” and shall have a deviation ratio of 16 plus or minus 1 (i.e. 15 to 17) when observed at any angle of elevation up to 5 degrees, with a minimum deviation ratio of 11 when observed at any angle of elevation above 5 degrees and up to 40 degrees;
- b) a 30 Hz amplitude modulation component:
 - i. Reserved (For Conventional VOR).
 - ii. for the Doppler VOR, this component, of constant phase with relation to azimuth and constant amplitude, is radiated omnidirectionally and is termed the “reference phase”.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 3

3.3.5.2 The nominal depth of modulation of the radio frequency carrier due to the 30 Hz signal or the subcarrier of 9 960 Hz shall be within the limits of 28 per cent and 32 per cent.

Note -This requirement applies to the transmitted signal observed in the absence of multipath.

3.3.5.3 The depth of modulation of the radio frequency carrier due to the 30 Hz signal, as observed at any angle of elevation up to 5 degrees, shall be within the limits of 25 to 35 per cent. The depth of modulation of the radio frequency carrier due to the 9 960 Hz signal, as observed at any angle of elevation up to 5 degrees, shall be within the limits of 20 to 55 per cent on facilities without voice modulation, and within the limits of 20 to 35 per cent on facilities with voice modulation.

Note. — When modulation is measured during flight testing under strong dynamic multipath conditions, variations in the received modulation percentages are to be expected. Short-term variations beyond these values may be acceptable. The Manual on Testing of Radio Navigation Aids (ICAO Doc 8071) contains additional information on the application of airborne modulation tolerances.

3.3.5.4 The variable and reference phase modulation frequencies shall be 30 Hz within plus or minus 1 per cent.

3.3.5.5 The subcarrier modulation mid-frequency shall be 9 960 Hz within plus or minus 1 per cent.

3.3.5.6

- a) Reserved (For Conventional VOR).
- b) For the Doppler VOR, the percentage of amplitude modulation of the 9 960 Hz subcarrier shall not exceed 40 per cent when measured at a point at least 300 m (1 000 ft) from the VOR.

3.3.5.7 Where 50 kHz VOR channel spacing is implemented, the sideband level of the harmonics of the 9 960 Hz component in the radiated signal shall not exceed the following levels referred to the level of the 9 960 Hz sideband:

<i>Subcarrier</i>	<i>Level</i>
9960Hz	0dB Reference
2 nd Harmonic	-30 dB
3 rd Harmonic	-50 dB
4 th Harmonic and above	-60 dB

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 4

3.3.6 Voice and identification

3.3.6.1 If the VOR provides a simultaneous communication channel ground-to-air, it shall be on the same radio frequency carrier as used for the navigational function. The radiation on this channel shall be horizontally polarized.

3.3.6.2 The peak modulation depth of the carrier on the communication channel shall not be greater than 30 per cent.

3.3.6.3 The audio frequency characteristics of the speech channel shall be within 3 dB relative to the level at 1 000 Hz over the range 300 Hz to 3 000 Hz.

3.3.6.4 The VOR shall provide for the simultaneous transmission of a signal of identification on the same radio frequency carrier as that used for the navigational function. The identification signal radiation shall be horizontally polarized.

3.3.6.5 The identification signal shall employ the International Morse Code and consist of two or three letters. It shall be sent at a speed corresponding to approximately 7 words per minute. The signal shall be repeated at least once every 30 seconds and the modulation tone shall be 1 020 Hz within plus or minus 50 Hz.

3.3.6.5.1 The identification signal should be transmitted at least three times each 30 seconds, spaced equally within that time period. One of these identification signals may take the form of a voice identification.

Note.— Where a VOR and DME are associated in accordance with 3.5.2.5, the identification provisions of 3.5.3.6.4 influence the VOR identification.

3.3.6.6 The depth to which the radio frequency carrier is modulated by the code identification signal shall be close to, but not in excess of 10 per cent except that, where a communication channel is not provided, it shall be permissible to increase the modulation by the code identification signal to a value not exceeding 20 per cent.

3.3.6.6.1 If the VOR provides a simultaneous communication channel ground-to-air, the modulation depth of the code identification signal should be 5 plus or minus 1 per cent in order to provide a satisfactory voice quality.

3.3.6.7 The transmission of speech shall not interfere in any way with the basic navigational function. When speech is being radiated, the code identification shall not be suppressed.

3.3.6.8 The VOR receiving function shall permit positive identification of the wanted signal under the signal conditions encountered within the specified coverage limits, and with the modulation parameters specified at 3.3.6.5, 3.3.6.6 and 3.3.6.7.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 5

3.3.7 Monitoring

3.3.7.1 Suitable equipment located in the radiation field shall provide signals for the operation of an automatic monitor. The monitor shall transmit a warning to a control point, and either remove the identification and navigation components from the carrier or cause radiation to cease if any one or a combination of the following deviations from established conditions arises:

- a) a change in excess of 1 degree at the monitor site of the bearing information transmitted by the VOR;
- b) a reduction of 15 per cent in the modulation components of the radio frequency signals voltage level at the monitor of either the subcarrier, or 30 Hz amplitude modulation signals, or both.

3.3.7.2 Failure of the monitor itself shall transmit a warning to a control point and either:

- a) remove the identification and navigation components from the carrier; or
- b) cause radiation to cease.

Note - Guidance material on VOR appears in Attachment C, 3, and Attachment E.

3.3.8 Interference immunity performance for VOR receiving systems

3.3.8.1 The VOR receiving system shall provide adequate immunity to interference from two signal, third-order intermodulation products caused by VHF FM broadcast signals having levels in accordance with the following:

$$2N_1 + N_2 + 72 \leq 0$$

for VHF FM sound broadcasting signals in the range 107.7 – 108.0 MHz
and

$$2N_1 + N_2 + 3 \left(24 - 20 \log \frac{\Delta f}{0.4} \right) \leq 0$$

for VHF FM sound broadcasting signals below 107.7 MHz,

where the frequencies of the two VHF FM sound broadcasting signals produce, within the receiver, a two-signal, third-order intermodulation product on the desired VOR frequency.

N_1 and N_2 are the levels (dBm) of the two VHF FM sound broadcasting signals at the VOR receiver input. Neither level shall exceed the desensitization criteria set forth in 3.3.8.2.

$f = 108.1 - f_1$, where f_1 is the frequency of N_1 , the VHF FM sound broadcasting signal closer to 108.1 MHz.

3.3.8.2 The VOR receiving system shall not be desensitized in the presence of VHF FM broadcast signals having levels in accordance with the following table:

Maximum level of

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 6

<i>Frequency (MHz)</i>	<i>unwanted signal at receiver input (dBm)</i>
88-102	+15
104	+10
106	+ 5
107.9	-10

Note 1- The relationship is linear between adjacent points designated by the above frequencies.

Note 2 - Guidance material on immunity criteria to be used for the performance quoted in 3.3.8.1 and 3.3.8.2 is contained in Attachment C, 3.6.5.

3.4 Specification for non-directional radio beacon (NDB)

3.4.1 Definitions

Note - In Attachment C, guidance is given on the meaning and application of rated coverage and effective coverage and on coverage of NDBs.

Average radius of rated coverage. The radius of a circle having the same area as the rated coverage.

Effective coverage. The area surrounding an NDB within which bearings can be obtained with an accuracy sufficient for the nature of the operation concerned.

Locator. An LF/MF NDB used as an aid to final approach.

Note - A locator usually has an average radius of rated coverage of between 18.5 and 46.3 km (10 and 25 NM).

Rated coverage. The area surrounding an NDB within which the strength of the vertical field of the ground wave exceeds the minimum value specified for the geographical area in which the radio beacon is situated.

Note - The above definition is intended to establish a method of rating radio beacons on the normal coverage to be expected in the absence of sky wave transmission and/or anomalous propagation from the radio beacon concerned or interference from other LF/MF facilities, but taking into account the atmospheric noise in the geographical area concerned.

3.4.2 Coverage

3.4.2.1 The minimum value of field strength in the rated coverage of an NDB should be 70^omicrovolts per meter.

Note 1- Guidance on the field strengths required particularly in the latitudes between 30°N and 30°S is given in 6.1 of Attachment C, and the relevant ITU provisions are given in Chapter VIII, Article 35, Section IV, Part B of the Radio Regulations.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 7

Note 2 - The selection of locations and times at which the field strength is measured is important in order to avoid abnormal results for the locality concerned; locations on air routes in the area around the beacon are operationally most significant.

3.4.2.2 All notifications or promulgations of NDBs shall be based upon the average radius of the rated coverage.

Note 1- In classifying radio beacons in areas where substantial variations in rated coverage may occur diurnally and seasonally, such variations should be taken into account.

Note 2 - Beacons having an average radius of rated coverage of between 46.3 and 278 km (25 and 150 NM) may be designated by the nearest multiple of 46.3 km (25 NM) to the average radius of rated coverage, and beacons of rated coverage over 278 km (150 NM) to the nearest multiple of 92.7 km (50 NM).

3.4.2.3 Where the rated coverage of an NDB is materially different in various operationally significant sectors, its classification should be expressed in terms of the average radius of rated coverage and the angular limits of each sector as follows:

Radius of coverage of sector/angular limits of sector expressed as magnetic bearing clockwise from the beacon.

Where it is desirable to classify an NDB in such a manner, the number of sectors should be kept to a minimum and preferably should not exceed two.

Note - The average radius of a given sector of the rated coverage is equal to the radius of the corresponding circle-sector of the same area. Example:

150/210° – 30°
100/30° – 210°

3.4.3 Limitations in radiated power

The power radiated from an NDB shall not exceed by more than 2 dB that necessary to achieve its agreed rated coverage, except that this power may be increased if coordinated regionally or if no harmful interference to other facilities will result.

3.4.4 Radio frequencies

3.4.4.1 The radio frequencies assigned to NDBs shall be selected from those available in that portion of the spectrum between 190 kHz and 1 750 kHz.

3.4.4.2 The frequency tolerance applicable to NDBs shall be 0.01 per cent except that, for NDBs of antenna power above 200 W using frequencies of 1 606.5 kHz and above, the tolerance shall be 0.005 per cent.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 8

3.4.4.3 Where two locators are used as supplements to an ILS, the frequency separation between the carriers of the two should be not less than 15 kHz to ensure correct operation of the radio compass, and preferably not more than 25 kHz in order to permit a quick tuning shift in cases where an aircraft has only one radio compass.

3.4.4.4 Where locators associated with ILS facilities serving opposite ends of a single runway are assigned a common frequency, provision shall be made to ensure that the facility not in operational use cannot radiate.

Note - Additional guidance on the operation of locator beacons on common frequency channels is contained in Volume V, Chapter 3, 3.2.2.

3.4.5 Identification

3.4.5.1 Each NDB shall be individually identified by a two- or three-letter International Morse Code group transmitted at a rate corresponding to approximately 7 words per minute.

3.4.5.2 The complete identification shall be transmitted at least once every 30 seconds, except where the beacon identification is effected by on/off keying of the carrier. In this latter case, the identification shall be at approximately 1-minute intervals, except that a shorter interval may be used at particular NDB stations where this is found to be operationally desirable.

3.4.5.2.1 Except for those cases where the beacon identification is effected by on/off keying of the carrier, the identification signal should be transmitted at least three times each 30 seconds, spaced equally within that time period.

3.4.5.3 For NDBs with an average radius of rated coverage of 92.7 km (50 NM) or less that are primarily approach and holding aids in the vicinity of an aerodrome, the identification shall be transmitted at least three times each 30 seconds, spaced equally within that time period.

3.4.5.4 The frequency of the modulating tone used for identification shall be 1 020 Hz plus or minus 50 Hz or 400 Hz plus or minus 25 Hz.

Note.-Determination of the figure to be used would be made regionally, in the light of the considerations contained in Attachment C, 6.5.

3.4.6 Characteristics of emissions

Note.-The following specifications are not intended to preclude employment of modulations or types of modulations that may be utilized in NDBs in addition to those specified for identification, including simultaneous identification and voice modulation, provided that these additional modulations do not materially affect the operational performance of the NDBs in conjunction with currently used airborne direction finders, and provided their use does not cause harmful interference to other NDB services.

3.4.6.1 Except as provided in 3.4.6.1.1, all NDBs shall radiate an uninterrupted carrier and be identified by on/off keying of an amplitude modulating tone (NON/A2A).

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 9

3.4.6.1.1 NDBs other than those wholly or partly serving as holding, approach and landing aids, or those having an average radius of rated coverage of less than 92.7 km (50 NM), may be identified by on/off keying of the unmodulated carrier (NON/A1A) if they are in areas of high beacon density and/or where the required rated coverage is not practicable of achievement because of:

- a) radio interference from radio stations;
- b) high atmospheric noise;
- c) local conditions.

Note. — In selecting the types of emission, the possibility of confusion, arising from an aircraft tuning from a NON/A2A facility to a NON/A1A facility without changing the radio compass from “MCW” to “CW” operation, will need to be kept in mind.

3.4.6.2 For each NDB identified by on/off keying of an audio modulating tone, the depth of modulation shall be maintained as near to 95 per cent as practicable.

3.4.6.3 For each NDB identified by on/off keying of an audio modulating tone, the characteristics of emission during identification shall be such as to ensure satisfactory identification at the limit of its rated coverage.

Note 1- The foregoing requirement necessitates as high a percentage modulation as practicable, together with maintenance of an adequate radiated carrier power during identification.

Note 2 - With a direction-finder pass band of plus or minus 3 kHz about the carrier, a signal to noise ratio of 6 dB at the limit of rated coverage will, in general, meet the foregoing requirement.

Note 3 - Some considerations with respect to modulation depth are contained in Attachment C, 6.4.

3.4.6.4 The carrier power of an NDB with NON/A2A emissions should not fall when the identity signal is being radiated except that, in the case of an NDB having an average radius of rated coverage exceeding 92.7 km (50 NM), a fall of not more than 1.5 dB may be accepted.

3.4.6.5 Unwanted audio frequency modulations shall total less than 5 per cent of the amplitude of the carrier.

Note - Reliable performance of airborne automatic direction-finding equipment (ADF) may be seriously prejudiced if the beacon emission contains modulation by an audio frequency equal or close to the loop switching frequency or its second harmonic. The loop switching frequencies in currently used equipment lie between 30 Hz and 120 Hz.

3.4.6.6 The bandwidth of emissions and the level of spurious emissions shall be kept at the lowest value that the state of technique and the nature of the service permit.

Note - Article S3 of the ITU Radio Regulations contains the general provisions with respect to technical characteristics of equipment and emissions. The Radio Regulations contain specific provisions relating to necessary bandwidth, frequency tolerance, spurious emissions and classification of emissions (see Appendices APS1, APS2 and APS3).

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 10

3.4.7 Siting of locators

3.4.7.1 Where locators are used as a supplement to the ILS, they should be located at the sites of the outer and middle marker beacons. Where only one locator is used as a supplement to the ILS, preference should be given to location at the site of the outer marker beacon. Where locators are employed as an aid to final approach in the absence of an ILS, equivalent locations to those applying when an ILS is installed should be selected, taking into account the relevant obstacle clearance provisions of the PANS-OPS (ICAO Doc 8168).

3.4.7.2 Where locators are installed at both the middle and outer marker positions, they should be located, where practicable, on the same side of the extended center line of the runway in order to provide a track between the locators which will be more nearly parallel to the center line of the runway.

3.4.8 Monitoring

3.4.8.1 For each NDB, suitable means shall be provided to enable detection of any of the following conditions at an appropriate location:

- a) a decrease in radiated carrier power of more than 50 per cent below that required for the rated coverage;
- b) failure to transmit the identification signal;
- c) malfunctioning or failure of the means of monitoring itself.

3.4.8.2 When an NDB is operated from a power source having a frequency which is close to airborne ADF equipment switching frequencies, and where the design of the NDB is such that the power supply frequency is likely to appear as a modulation product on the emission, the means of monitoring should be capable of detecting such power supply modulation on the carrier in excess of 5 per cent.

3.4.8.3 During the hours of service of a locator, the means of monitoring shall provide for a continuous check on the functioning of the locator as prescribed in 3.4.8.1 a), b) and c).

3.4.8.4 During the hours of service of an NDB other than a locator, the means of monitoring should provide for a continuous check on the functioning of the NDB as prescribed in 3.4.8.1 a), b) and c).

Note - Guidance material on the testing of NDBs is contained in 6.6 of Attachment C.

3.5 Specification for UHF distance measuring equipment (DME)

Note - In the following section, provision is made for two types of DME facility: DME/N for general application, and DME/P as outlined in 3.11.3.

3.5.1 Definitions

Control motion noise (CMN). That portion of the guidance signal error which causes control surface, wheel and column motion and could affect aircraft attitude angle during coupled flight, but does not cause aircraft displacement from the desired course and/or glide path. (See 3.11.)

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 11

DME dead time. A period immediately following the decoding of a valid interrogation during which a received interrogation will not cause a reply to be generated.

Note - Dead time is intended to prevent the transponder from replying to echoes resulting from multipath effects.

DME/N. Distance measuring equipment, primarily serving operational needs of en-route or TMA navigation, where the “N” stands for narrow spectrum characteristics.

DME/P. The distance measuring element of the MLS, where the “P” stands for precise distance measurement. The spectrum characteristics are those of DME/N.

Equivalent isotropically radiated power (EIRP). The product of the power supplied to the antenna and the antenna gain in a given direction relative to an isotropic antenna (absolute or isotropic gain).

Final approach (FA) mode. The condition of DME/P operation which supports flight operations in the final approach and runway regions.

Initial approach (IA) mode. The condition of DME/P operation which supports those flight operations outside the final approach region and which is interoperable with DME/N.

Key down time. The time during which a dot or dash of a Morse character is being transmitted.

MLS approach reference datum. A point on the minimum glide path at a specified height above the threshold. (See 3.11.)

MLS datum point. The point on the runway centre line closest to the phase centre of the approach elevation antenna. (See 3.11.)

Mode W, X, Y, Z. A method of coding the DME transmissions by time spacing pulses of a pulse pair, so that each frequency can be used more than once.

Partial rise time. The time as measured between the 5 and 30 per cent amplitude points on the leading edge of the pulse envelope, i.e. between points h and i on Figures 3-1 and 3-2.

Path following error (PFE). That portion of the guidance signal error which could cause aircraft displacement from the desired course and/or glide path. (See 3.11.)

Pulse amplitude. The maximum voltage of the pulse envelope, i.e. A in Figure 3-1.

Pulse decay time. The time as measured between the 90 and 10 per cent amplitude points on the trailing edge of the pulse envelope, i.e. between points e and g on Figure 3-1.

Pulse code. The method of differentiating between W, X, Y and Z modes and between FA and IA modes.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 12

Pulse duration. The time interval between the 50 per cent amplitude point on leading and trailing edges of the pulse envelope, i.e. between points b and f on Figure 3-1.

Pulse rise time. The time as measured between the 10 and 90 per cent amplitude points on the leading edge of the pulse envelope, i.e. between points a and c on Figure 3-1.

Reply efficiency. The ratio of replies transmitted by the transponder to the total of received valid interrogations.

Search. The condition which exists when the DME interrogator is attempting to acquire and lock onto the response to its own interrogations from the selected transponder.

System efficiency. The ratio of valid replies processed by the interrogator to the total of its own interrogations.

Track. The condition which exists when the DME interrogator has locked onto replies in response to its own interrogations, and is continuously providing a distance measurement.

Transmission rate. The average number of pulse pairs transmitted from the transponder per second.

Virtual origin. The point at which the straight line through the 30 per cent and 5 per cent amplitude points on the pulse leading edge intersects the 0 per cent amplitude axis (see Figure 3-2).

————— INTENTIONALLY LEFT BLANK —————

Figure 3-1

Figure 3-2

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 14

3.5.2 General

3.5.2.1 The DME system shall provide for continuous and accurate indication in the cockpit of the slant range distance of an equipped aircraft from an equipped ground reference point.

3.5.2.2 The system shall comprise two basic components, one fitted in the aircraft, the other installed on the ground. The aircraft component shall be referred to as the interrogator and the ground component as the transponder.

3.5.2.3 In operation, interrogators shall interrogate transponders which shall, in turn, transmit to the interrogator replies synchronized with the interrogations, thus providing means for accurate measurement of distance.

3.5.2.4 (Reserved) DME/P Operating modes

3.5.2.5 When a DME is associated with VOR for the purpose of constituting a single facility, they shall:

- a) be operated on a standard frequency pairing in accordance with 3.5.3.3.4;
- b) be collocated within the limits prescribed for associated facilities in 3.5.2.6; and
- c) comply with the identification provisions of 3.5.3.6.4.

3.5.2.6 Collocation limits for a DME facility associated with VOR facility.

3.5.2.6.1 Associated VOR and DME facilities shall be collocated in accordance with the following:

- a) for those facilities used in terminal areas for approach purposes or other procedures where the highest position fixing accuracy of system capability is required, the separation of the VOR and DME antennas does not exceed 80 m (260 ft);
- b) for purposes other than those indicated in a), the separation of the VOR and DME antennas does not exceed 600 m (2 000 ft).

3.5.2.6.2 (Reserved) Association of DME with ILS

3.5.2.6.3 (Reserved) Association of DME with MLS

3.5.2.7 The Standards in 3.5.3, 3.5.4 and 3.5.5 denoted by ‡ shall apply only to DME equipment first installed after 1 January 1989.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 15

3.5.3 System characteristics

3.5.3.1 Performance

3.5.3.1.1 Range. The system shall provide a means of measurement of slant range distance from an aircraft to a selected transponder to the limit of coverage prescribed by the operational requirements for the selected transponder.

3.5.3.1.2 Coverage

3.5.3.1.2.1 When associated with a VOR, DME/N coverage shall be at least that of the VOR to the extent practicable.

3.5.3.1.2.2 (Reserved) Coverage associated with MLS and ILS

3.5.3.1.2.3 (Reserved) DME/P Coverage

Note - This is not intended to specify the operational range and coverage to which the system may be used; spacing of facilities already installed may limit the range in certain areas.

3.5.3.1.3 Accuracy

3.5.3.1.3.1 System accuracy. The accuracy standards specified in 3.5.3.1.4, 3.5.4.5 and 3.5.5.4 shall be met on a 95 per cent probability basis.

3.5.3.1.4 (Reserved) DME/P Accuracy

3.5.3.2 Radio frequencies and polarization. The system shall operate with vertical polarization in the frequency band 960 MHz to 1 215 MHz. The interrogation and reply frequencies shall be assigned with 1MHz spacing between channels.

3.5.3.3 Channelling

3.5.3.3.1 DME operating channels shall be formed by pairing interrogation and reply frequencies and by pulse coding on the paired frequencies.

3.5.3.3.2 (Reserved) DME/P Pulse Coding

3.5.3.3.3 DME operating channels shall be chosen from Table A (located at the end of this chapter), of 352 channels in which the channel numbers, frequencies, and pulse codes are assigned.

3.5.3.3.4 Channel pairing. When a DME transponder is intended to operate in association with a single VHF navigation facility in the 108 MHz to 117.95 MHz frequency band and/or an MLS angle facility in the 5 031.0 MHz to 5 090.7 MHz frequency band, the DME operating channel shall be paired with the VHF channel and/or MLS angle frequency as given in Table A.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 16

3.5.3.4 Interrogation pulse repetition frequency

Note - If the interrogator operates on more than one channel in one second, the following specifications apply to the sum of interrogations on all channels.

3.5.3.4.1 DME/N. The interrogator average pulse repetition frequency (PRF) shall not exceed 30 pairs of pulses per second, based on the assumption that at least 95 per cent of the time is occupied for tracking.

3.5.3.4.2 DME/N. If it is desired to decrease the time of search, the PRF may be increased during search but shall not exceed 150 pairs of pulses per second.

3.5.3.4.3 DME/N. After 15 000 pairs of pulses have been transmitted without acquiring indication of distance, the PRF should not exceed 60 pairs of pulses per second thereafter, until a change in operating channel is made or successful search is completed.

3.5.3.4.4 DME/N. When, after a time period of 30 seconds, tracking has not been established, the pulse pair repetition frequency shall not exceed 30 pulse pairs per second thereafter.

3.5.3.4.5 (Reserved) DME/P Pulse pair limitation per second

3.5.3.5 Aircraft handling capacity of the system

3.5.3.5.1 The aircraft handling capacity of transponders in an area shall be adequate for the peak traffic of the area or 100 aircraft, whichever is the lesser.

3.5.3.5.2 Where the peak traffic in an area exceeds 100 aircraft, the transponder should be capable of handling that peak traffic.

Note - Guidance material on aircraft handling capacity will be found in Attachment C, 7.1.5.

3.5.3.6 Transponder identification

3.5.3.6.1 All transponders shall transmit an identification signal in one of the following forms as required by 3.5.3.6.5:

- a) an “independent” identification consisting of coded (International Morse Code) identity pulses which can be used with all transponders;
- b) an “associated” signal which can be used for transponders specifically associated with a VHF navigation or an MLS angle guidance facility which itself transmits an identification signal.

3.5.3.6.2 Both systems of identification shall use signals, which shall consist of the transmission for an appropriate period of a series of paired pulses transmitted at a repetition rate of 1 350 pulse pairs per second, and shall temporarily replace all reply pulses that would normally occur at that time except as in 3.5.3.6.2.2. These pulses shall have similar characteristics to the other pulses of the reply signals.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 17

3.5.3.6.2.1 DME/N. Reply pulses shall be transmitted between key down times.

3.5.3.6.2.2 DME/N. If it is desired to preserve a constant duty cycle, an equalizing pair of pulses, having the same characteristics as the identification pulse pairs, should be transmitted 100 microseconds plus or minus 10 microseconds after each identity pair.

3.5.3.6.2.3(Reserved) DME/P Reply pulses

3.5.3.6.2.4 (Reserved) DME/P Transponder

3.5.3.6.2.5 (Reserved) DME/P Transponder

3.5.3.6.3 The characteristics of the “independent” identification signal shall be as follows:

- a) the identity signal shall consist of the transmission of the beacon code in the form of dots and dashes (International Morse Code) of identity pulses at least once every 40 seconds, at a rate of at least 6 words per minute; and
- b) the identification code characteristic and letter rate for the DME transponder shall conform to the following to ensure that the maximum total key down time does not exceed 5 seconds per identification code group. The dots shall be a time duration of 0.1 second to 0.160 second. The dashes shall be typically 3 times the duration of the dots. The duration between dots and/or dashes shall be equal to that of one dot plus or minus 10 per cent. The time duration between letters or numerals shall not be less than three dots. The total period for transmission of an identification code group shall not exceed 10 seconds.

Note - The tone identification signal is transmitted at a repetition rate of 1 350 pps. This frequency may be used directly in the airborne equipment as an aural output for the pilot, or other frequencies may be generated at the option of the interrogator designer (see 3.5.3.6.2).

3.5.3.6.4 The characteristics of the “associated” signal shall be as follows:

- a) when associated with a VHF or an MLS angle facility, the identification shall be transmitted in the form of dots and dashes (International Morse Code) as in 3.5.3.6.3 and shall be synchronized with the VHF facility identification code;
- b) each 40-second interval shall be divided into four or more equal periods, with the transponder identification transmitted during one period only and the associated VHF and MLS angle facility identification, where these are provided, transmitted during the remaining periods;
- c) (Reserved) DME Transponder associated with MLS

3.5.3.6.5 Identification implementation

3.5.3.6.5.1 The “independent” identification code shall be employed wherever a transponder is not specifically associated with a VHF navigational facility or an MLS facility.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 18

3.5.3.6.5.2 Wherever a transponder is specifically associated with a VHF navigational facility identification shall be provided by the “associated” code.

3.5.3.6.5.3 When voice communications are being radiated on an associated VHF navigational facility, an “associated” signal from the transponder shall not be suppressed.

3.5.3.7 (Reserved) DME/P mode transition

3.5.3.7 (Reserved) DME/P System efficiency

3.5.4 Detailed technical characteristics of transponder and associated monitor

3.5.4.1 Transmitter

3.5.4.1.1 Frequency of operation. The transponder shall transmit on the reply frequency appropriate to the assigned DME channel (see 3.5.3.3.3).

3.5.4.1.2 Frequency stability. The radio frequency of operation shall not vary more than plus or minus 0.002 per cent from the assigned frequency.

3.5.4.1.3 Pulse shape and spectrum. The following shall apply to all radiated pulses:

- a) Pulse rise time.
 - i. DME/N. Pulse rise time shall not exceed 3 microseconds.
 - ii. (Reserved) DME/P Pulse rise time
- b) Pulse duration shall be 3.5 microseconds plus or minus 0.5 microsecond.
- c) Pulse decay time shall nominally be 2.5 microseconds but shall not exceed 3.5 microseconds.
- d) The instantaneous amplitude of the pulse shall not, at any instant between the point of the leading edge which is 95 per cent of maximum amplitude and the point of the trailing edge which is 95 per cent of the maximum amplitude, fall below a value which is 95 per cent of the maximum voltage amplitude of the pulse.
- e) For DME/N: the spectrum of the pulse modulated signal shall be such that during the pulse the EIRP contained in a 0.5 MHz band centered on frequencies 0.8 MHz above and 0.8 MHz below the nominal channel frequency in each case shall not exceed 200 mW, and the EIRP contained in a 0.5 MHz band centered on frequencies 2 MHz above and 2 MHz below the nominal channel frequency in each case shall not exceed 2 mW. The EIRP contained within any 0.5 MHz band shall decrease monotonically as the band center frequency moves away from the nominal channel frequency.

Note. — Guidance material relating to the pulse spectrum measurement is provided in Document EUROCAE ED-57 (including Amendment No. 1).

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 19

- f) To ensure proper operation of the thresholding techniques, the instantaneous magnitude of any pulse turn-on transients which occur in time prior to the virtual origin shall be less than one per cent of the pulse peak amplitude. Initiation of the turn-on process shall not commence sooner than 1 microsecond prior to the virtual origin.

Note 1. — The time “during the pulse” encompasses the total interval from the beginning of pulse transmission to its end. For practical reasons, this interval may be measured between the 5 per cent points on the leading and trailing edges of the pulse envelope.

Note 2. — The power contained in the frequency bands specified in 3.5.4.1.3 e) is the average power during the pulse. Average power in a given frequency band is the energy contained in this frequency band divided by the time of pulse transmission according to Note 1.

3.5.4.1.4 Pulse spacing

3.5.4.1.4.1 The spacing of the constituent pulses of transmitted pulse pairs shall be as given in the table in 3.5.4.4.1.

3.5.4.1.4.2 DME/N. The tolerance on the pulse spacing shall be plus or minus 0.25 microsecond.

3.5.4.1.4.3 DME/N. The tolerance on the DME/N pulse spacing should be plus or minus 0.10 microsecond.

3.5.4.1.4.4 (Reserved) DME/P Tolerance

3.5.4.1.4.5 The pulse spacing shall be measured between the half voltage points on the leading edges of the pulses.

3.5.4.1.5 Peak power output

3.5.4.1.5.1 DME/N. The peak EIRP should not be less than that required to ensure a peak pulse power density of approximately minus 83 dBW/m² at the maximum specified service range and level.

3.5.4.1.5.2 DME/N. The peak equivalent isotropically radiated power shall not be less than that required to ensure a peak pulse power density of minus 89 dBW/m² under all operational weather conditions at any point within coverage specified in 3.5.3.1.2.

3.5.4.1.5.3 (Reserved) DME/P Peak EIRP

Note. — Although the Standard in 3.5.4.1.5.2 implies an improved interrogator receiver sensitivity, it is intended that the power density specified in 3.5.4.1.5.1 be available at the maximum specified service range and level.

3.5.4.1.5.4 The peak power of the constituent pulses of any pair of pulses shall not differ by more than 1 dB.

3.5.4.1.5.4.5 The reply capability of the transmitter should be such that the transponder should be capable of continuous operation at a transmission rate of 2 700 plus or minus 90 pulse pairs per second (if 100 aircraft are to be served).

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 20

Note - Guidance on the relationship between number of aircraft and transmission rate is given in Attachment C, 7.1.5.

3.5.4.1.5.5.6 The transmitter shall operate at a transmission rate, including randomly distributed pulse pairs and distance reply pulse pairs, of not less than 700 pulse pairs per second except during identity. The minimum transmission rate shall be as close as practicable to 700 pulse pairs per second.

Note - Operating DME transponders with quiescent transmission rates close to 700 pulse pairs per second will minimize the effects of pulse interference, particularly to other aviation services such as GNSS.

3.5.4.1.6 Spurious radiation. During intervals between transmission of individual pulses, the spurious power received and measured in a receiver having the same characteristics as a transponder receiver, but tuned to any DME interrogation or reply frequency, shall be more than 50 dB below the peak pulse power received and measured in the same receiver tuned to the reply frequency in use during the transmission of the required pulses. This provision refers to all spurious transmissions, including modulator and electrical interference.

3.5.4.1.6.1 DME/N. The spurious power level specified in 3.5.4.1.6 shall be more than 80 dB below the peak pulse power level.

3.5.4.1.6.2 (Reserved) DME/P Spurious Power

3.5.4.1.6.3 Out-of-band spurious radiation. At all frequencies from 10 to 1 800 MHz, but excluding the band of frequencies from 960 to 1 215 MHz, the spurious output of the DME transponder transmitter shall not exceed minus 40 dBm in any one kHz of receiver bandwidth.

3.5.4.1.6.4 The equivalent isotropically radiated power of any CW harmonic of the carrier frequency on any DME operating channel shall not exceed minus 10 dBm.

3.5.4.2 Receiver

3.5.4.2.1 Frequency of operation. The receiver center frequency shall be the interrogation frequency appropriate to the assigned DME operating channel (see 3.5.3.3.3).

3.5.4.2.2 Frequency stability. The center frequency of the receiver shall not vary more than plus or minus 0.002 per cent from the assigned frequency.

3.5.4.2.3 Transponder sensitivity

3.5.4.2.3.1 In the absence of all interrogation pulse pairs, with the exception of those necessary to perform the sensitivity measurement, interrogation pulse pairs with the correct spacing and nominal frequency shall trigger the transponder if the peak power density at the transponder antenna is at least:

- a) minus 103 dBW/m² for DME/N with coverage range greater than 56 km (30 NM);
- b) minus 93 dBW/m² for DME/N with coverage range not greater than 56 km (30 NM);

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 21

c) (Reserved) DME/P IA Mode

d) (Reserved) DME/P FA Mode

3.5.4.2.3.2 The minimum power densities specified in 3.5.4.2.3.1 shall cause the transponder to reply with an efficiency of at least:

a) 70 per cent for DME/N;

b) (Reserved) DME/P IA Mode

c) (Reserved) DME/P FA Mode

3.5.4.2.3.3 DME/N dynamic range. The performance of the transponder shall be maintained when the power density of the interrogation signal at the transponder antenna has any value between the minimum specified in 3.5.4.2.3.1 up to a maximum of minus 22 dBW/m² when installed with ILS or MLS and minus 35 dBW/m² when installed for other applications.

3.5.4.2.3.4 (Reserved) DME/P dynamic range.

3.5.4.2.3.5 The transponder sensitivity level shall not vary by more than 1 dB for transponder loadings between 0 and 90 per cent of its maximum transmission rate.

3.5.4.2.3.6 DME/N. When the spacing of an interrogator pulse pair varies from the nominal value by up to plus or minus 1 microsecond, the receiver sensitivity shall not be reduced by more than 1 dB.

3.5.4.2.3.7 (Reserved) DME/P Sensitivity

3.5.4.2.4 Load limiting

3.5.4.2.4.1 DME/N. When transponder loading exceeds 90 per cent of the maximum transmission rate, the receiver sensitivity should be automatically reduced in order to limit the transponder replies, so as to ensure that the maximum permissible transmission rate is not exceeded. (The available range of sensitivity reduction should be at least 50 dB.)

3.5.4.2.4.2 (Reserved) DME/P loading

3.5.4.2.5 Noise. When the receiver is interrogated at the power densities specified in 3.5.4.2.3.1 to produce a transmission rate equal to 90 per cent of the maximum, the noise generated pulse pairs shall not exceed 5 per cent of the maximum transmission rate.

3.5.4.2.6 Bandwidth

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 22

3.5.4.2.6.1 The minimum permissible bandwidth of the receiver shall be such that the transponder sensitivity level shall not deteriorate by more than 3 dB when the total receiver drift is added to an incoming interrogation frequency drift of plus or minus 100 kHz.

3.5.4.2.6.2 DME/N. The receiver bandwidth shall be sufficient to allow compliance with 3.5.3.1.3 when the input signals are those specified in 3.5.5.1.3.

3.5.4.2.6.3 (Reserved) DME/N IA-Mode

3.5.4.2.6.4 (Reserved) DME/N FA-Mode

3.5.4.2.6.5 Signals greater than 900 kHz removed from the desired channel nominal frequency and having power densities up to the values specified in 3.5.4.2.3.3 for DME/N shall not trigger the transponder. Signals arriving at the intermediate frequency shall be suppressed at least 80 dB. All other spurious response or signals within the 960 MHz to 1 215 MHz band and image frequencies shall be suppressed at least 75 dB.

3.5.4.2.7 Recovery time. Within 8 microseconds of the reception of a signal between 0 dB and 60 dB above minimum sensitivity level, the minimum sensitivity level of the transponder to a desired signal shall be within 3 dB of the value obtained in the absence of signals. This requirement shall be met with echo suppression circuits, if any, rendered inoperative. The 8 microseconds are to be measured between the half voltage points on the leading edges of the two signals, both of which conform in shape, with the specifications in 3.5.5.1.3.

3.5.4.2.8 Spurious radiations. Radiation from any part of the receiver or allied circuits shall meet the requirements stated in 3.5.4.1.6.

3.5.4.2.9 CW and echo suppression

CW and echo suppression should be adequate for the sites at which the transponders will be used.

Note - In this connection, echoes mean undesired signals caused by multipath transmission (reflections, etc.).

3.5.4.2.10 Protection against interference

Protection against interference outside the DME frequency band should be adequate for the sites at which the transponders will be used.

3.5.4.3 Decoding

3.5.4.3.1 The transponder shall include a decoding circuit such that the transponder can be triggered only by pairs of received pulses having pulse duration and pulse spacings appropriate to interrogator signals as described in 3.5.5.1.3 and 3.5.5.1.4

3.5.4.3.2 The decoding circuit performance shall not be affected by signals arriving before, between, or after, the constituent pulses of a pair of the correct spacing.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

3.5.4.3.3 DME/N- Decoder rejection. An interrogation pulse pair with a spacing of plus or minus 2 microseconds, or more, from the nominal value and with any signal level up to the value specified in 3.5.4.2.3.3 shall be rejected such that the transmission rate does not exceed the value obtained when interrogations are absent.

3.5.4.3.4 (Reserved)DME/P- Decoder rejection.

3.5.4.4 Time delay

3.5.4.4.1 When a DME is associated only with a VHF facility, the time delay shall be the interval from the half voltage point on the leading edge of the second constituent pulse of the interrogation pair and the half voltage point on the leading edge of the second constituent pulse of the reply transmission. This delay shall be consistent with the following table, when it is desired that aircraft interrogators are to indicate distance from the transponder site.

Channel suffix	Operating mode	Pulse pair spacing (μ s)		Time delay (μ s)	
		Interrogation	Reply	1st pulse timing	2nd pulse timing
X	DME/N	12	12	50	50
	DME/P IA M	12	12	50	–
	DME/P FA M	18	12	56	–
Y	DME/N	36	30	56	50
	DME/P IA M	36	30	56	–
	DME/P FA M	42	30	62	–
W	DME/N	–	–	–	–
	DME/P IA M	24	24	50	–
	DME/P FA M	30	24	56	–
Z	DME/N	–	–	–	–
	DME/P IA M	21	15	56	–
	DME/P FA M	27	15	62	–

Note 1.— W and X are multiplexed on the same frequency.

Note 2.— Z and Y are multiplexed on the same frequency.

3.5.4.4.2 When a DME is associated with an MLS angle facility, the time delay shall be the interval from the half voltage point on the leading edge of the first constituent pulse of the interrogation pair and the half voltage point on the leading edge of the first constituent pulse of the reply transmission. This delay shall be 50 microseconds for mode X channels and 56 microseconds for mode Y channels, when it is desired that aircraft interrogators are to indicate distance from the transponder site.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 24

3.5.4.4.2.1 DME/P transponder, no time delay adjustment shall be permitted.

3.5.4.4.3 For the DME/N the transponder time delay should be capable of being set to an appropriate value between the nominal value of the time delay minus 15 microseconds and the nominal value of the time delay, to permit aircraft interrogators to indicate zero distance at a specific point remote from the transponder site.

Note.— Modes not allowing for the full 15 microseconds range of adjustment in transponder time delay may only be adjustable to the limits given by the transponder circuit delay and recovery time.

3.5.4.4.3.1 DME/N. The time delay shall be the interval from the half voltage point on the leading edge of the first constituent pulse of the interrogation pair and the half voltage point on the leading edge of the first constituent pulse of the reply transmission.

3.5.4.4.3.2 (Reserved) DME/N IA-Mode

3.5.4.4.3.3 (Reserved) DME/N FA-Mode

3.5.4.4.4 DME/N. Transponders should be sited as near to the point at which zero indication is required as is practicable.

Note 1. — It is desirable that the radius of the sphere at the surface of which zero indication is given be kept as small as possible in order to keep the zone of ambiguity to a minimum.

3.5.4.5 Accuracy

3.5.4.5.1 DME/N. The transponder shall not contribute more than plus or minus 1 microsecond (150 m (500 ft)) to the overall system error.

3.5.4.5.1.1 DME/N. The contribution to the total system error due to the combination of the transponder errors, transponder location coordinate errors, propagation effects and random pulse interference effects should be not greater than plus or minus 340 m (0.183 NM) plus 1.25 per cent of distance measure.

Note. — This error contribution limit includes errors from all causes except the airborne equipment, and assumes that the airborne equipment measures time delay based on the first constituent pulse of a pulse pair.

3.5.4.5.1.2 DME/N. The combination of the transponder errors, transponder location coordinate errors, propagation effects and random pulse interference effects shall not contribute more than plus or minus 185 m (0.1 NM) to the overall system error.

Note. — This error contribution limit includes errors from all causes except the airborne equipment, and assumes that the airborne equipment measures time delay based on the first constituent pulse of a pulse pair.

3.5.4.5.2 DME/N. A transponder associated with a landing aid shall not contribute more than plus or minus 0.5 microsecond (75 m (250 ft)) to the overall system error.

3.5.4.5.3 (Reserved) DME/P FA-Mode

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 25

3.5.4.5.4 (Reserved) DME/P IA-Mode

3.5.4.5.6 When a DME is associated with an MLS angle facility, the above accuracy should include the error introduced by the first pulse detection due to the pulse spacing tolerances.

3.5.4.6 Efficiency

3.5.4.6.1 The transponder reply efficiency shall be at least 70 per cent for DME/N at all values of transponder loading up to the loading corresponding to 3.5.3.5 and at the minimum sensitivity level specified in 3.5.4.2.3.1 and 3.5.4.2.3.5.

Note.— When considering the transponder reply efficiency value, account is to be taken of the DME dead time and of the loading introduced by the monitoring function.

3.5.4.6.2 Transponder dead time. The transponder shall be rendered inoperative for a period normally not to exceed 60 microseconds after a valid interrogation decode has occurred. In extreme cases when the geographical site of the transponder is such as to produce undesirable reflection problems, the dead time may be increased but only by the minimum amount necessary to allow the suppression of echoes for DME/N.

3.5.4.6.2.1 (Reserved) DME/P Dead time

3.5.4.7 Monitoring and control

3.5.4.7.1 Means shall be provided at each transponder site for the automatic monitoring and control of the transponder in use.

3.5.4.7.2 DME/N monitoring action

3.5.4.7.2.1 In the event that any of the conditions specified in 3.5.4.7.2.2 occur, the monitor shall cause the following action to take place:

- a) a suitable indication shall be given at a control point;
- b) the operating transponder shall be automatically switched off; and
- c) the standby transponder, if provided, shall be automatically placed in operation.

3.5.4.7.2.2 The monitor shall cause the actions specified in 3.5.4.7.2.1 if:

- a) the transponder delay differs from the assigned value by 1 microsecond (150 m (500 ft)) or more;
- b) in the case of a DME/N associated with a landing aid, the transponder delay differs from the assigned value by 0.5 microsecond (75 m (250 ft)) or more.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 26

3.5.4.7.2.3 The monitor should cause the actions specified in 3.5.4.7.2.1 if the spacing between the first and second pulse of the transponder pulse pair differs from the nominal value specified in the table following 3.5.4.4.1 by 1 microsecond or more.

3.5.4.7.2.4 The monitor should also cause a suitable indication to be given at a control point if any of the following conditions arise:

- a) a fall of 3 dB or more in transponder transmitted power output;
- b) a fall of 6 dB or more in the minimum transponder receiver sensitivity (provided that this is not due to the action of the receiver automatic gain reduction circuits);
- c) the spacing between the first and second pulse of the transponder reply pulse pair differs from the normal value specified in 3.5.4.1.4 by 1 microsecond or more;
- d) variation of the transponder receiver and transmitter frequencies beyond the control range of the reference circuits (if the operating frequencies are not directly *crystal controlled*).

3.5.4.7.2.5 Means shall be provided so that any of the conditions and malfunctioning enumerated in 3.5.4.7.2.2, 3.5.4.7.2.3 and 3.5.4.7.2.4 which are monitored can persist for a certain period before the monitor takes action. This period shall be as low as practicable, but shall not exceed 10 seconds, consistent with the need for avoiding interruption, due to transient effects, of the service provided by the transponder.

3.5.4.7.2.6 The transponder shall not be triggered more than 120 times per second for either monitoring or automatic frequency control purposes, or both.

3.5.4.7.3 (Reserved) DME/P Monitoring Control

3.5.5 Technical characteristics of interrogator

Note - The following subparagraphs specify only those interrogator parameters which must be defined to ensure that the interrogator:

- i. does not jeopardize the effective operation of the DME system, e.g. by increasing transponder loading abnormally; and*
- ii. is capable of giving accurate distance readings.*

3.5.5.1 Transmitter

3.5.5.1.1 Frequency of operation. The interrogator shall transmit on the interrogation frequency appropriate to the assigned DME channel (see 3.5.3.3.3).

Note - This specification does not preclude the use of airborne interrogators having less than the total number of operating channels.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 27

3.5.5.1.2 Frequency stability. The radio frequency of operation shall not vary more than plus or minus 100 kHz from the assigned value.

3.5.5.1.3 Pulse shape and spectrum. The following shall apply to all radiated pulses:

- a) Pulse rise time.
 - i. DME/N. Pulse rise time shall not exceed 3 microseconds.
 - ii. (Reserved) DME/P Pulse rise time
- b) Pulse duration shall be 3.5 microseconds plus or minus 0.5 microsecond.
- c) Pulse decay time shall nominally be 2.5 microseconds, but shall not exceed 3.5 microseconds.
- d) The instantaneous amplitude of the pulse shall not, at any instant between the point of the leading edge which is 95 per cent of maximum amplitude and the point of the trailing edge which is 95 per cent of the maximum amplitude, fall below a value which is 95 per cent of the maximum voltage amplitude of the pulse.
- e) The spectrum of the pulse modulated signal shall be such that at least 90 per cent of the energy in each pulse shall be within 0.5 MHz in a band centered on the nominal channel frequency.
- f) To ensure proper operation of the thresholding techniques, the instantaneous magnitude of any pulse turn-on transients which occur in time prior to the virtual origin shall be less than one per cent of the pulse peak amplitude. Initiation of the turn-on process shall not commence sooner than 1 microsecond prior to the virtual origin.

Note 1 - The lower limit of pulse rise time (see 3.5. 5.1.3 a)) and decay time (see 3.5.5.1.3 c)) are governed by the spectrum requirements in 3.5.5.1.3 e).

Note 2 - While 3.5.5.1.3 e) calls for a practically attainable spectrum, it is desirable to strive for the following spectrum control characteristics: the spectrum of the pulse modulated signal is such that the power contained in a 0.5 MHz band centered on frequencies 0.8 MHz above and 0.8 MHz below the nominal channel frequency is, in each case, at least 23 dB below the power contained in a 0.5 MHz band centered on the nominal channel frequency. The power contained in a 0.5 MHz band centered on frequencies 2 MHz above and 2 MHz below the nominal channel frequency is, in each case, at least 38 dB below the power contained in a 0.5 MHz band centered on the nominal channel frequency. Any additional lobe of the spectrum is of less amplitude than the adjacent lobe nearer the nominal channel frequency.

3.5.5.1.4 Pulse spacing

3.5.5.1.4.1 The spacing of the constituent pulses of transmitted pulse pairs shall be as given in the table in 3.5.4.4.1.

3.5.5.1.4.2 DME/N. The tolerance on the pulse spacing shall be plus or minus 0.5 microsecond.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 28

3.5.5.1.4.3 DME/N. The tolerance on the pulse spacing should be plus or minus 0.25 micro-second.

3.5.5.1.4.4 (Reserved) DME/P Tolerance.

3.5.5.1.4.5 The pulse spacing shall be measured between the half voltage points on the leading edges of the pulses.

3.5.5.1.5 Pulse repetition frequency

3.5.5.1.5.1 The pulse repetition frequency shall be as specified in 3.5.3.4.

3.5.5.1.5.2 The variation in time between successive pairs of interrogation pulses shall be sufficient to prevent false lock-on.

3.5.5.1.5.3 (Reserved) DME/P System accuracy

3.5.5.1.6 Spurious radiation. During intervals between transmission of individual pulses, the spurious pulse power received and measured in a receiver having the same characteristics of a DME transponder receiver, but tuned to any DME interrogation or reply frequency, shall be more than 50 dB below the peak pulse power received and measured in the same receiver tuned to the interrogation frequency in use during the transmission of the required pulses. This provision shall apply to all spurious pulse transmissions. The spurious CW power radiated from the interrogator on any DME interrogation or reply frequency shall not exceed 20 microwatts (minus 47 dBW).

Note - Although spurious CW radiation between pulses is limited to levels not exceeding minus 47 dBW, States are cautioned that where DME interrogators and secondary surveillance radar transponders are employed in the same aircraft, it may be necessary to provide protection to airborne SSR in the band 1 015 MHz to 1 045 MHz. This protection may be provided by limiting conducted and radiated CW to a level of the order of minus 77 dBW. Where this level cannot be achieved, the required degree of protection may be provided in planning the relative location of the SSR and DME aircraft antennas. It is to be noted that only a few of these frequencies are utilized in the VHF/DME pairing plan.

3.5.5.1.7 The spurious pulse power received and measured under the conditions stated in 3.5.5.1.6 should be 80 dB below the required peak pulse power received.

Note - Reference 3.5.5.1.6 and 3.5.5.1.7 — although limitation of spurious CW radiation between pulses to levels not exceeding 80 dB below the peak pulse power received is recommended, it is cautioned that where users employ airborne secondary surveillance radar transponders in the same aircraft, it may be necessary to limit direct and radiated CW to not more than 0.02 microwatt in the frequency band 1 015 MHz to 1 045 MHz. It is to be noted that only a few of these frequencies are utilized in the VHF/DME pairing plan.

3.5.5.1.8 (Reserved) DME/P EIRP

3.5.5.2 Time delay

3.5.5.2.1 The time delay shall be consistent with the table in 3.5.4.4.1.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 29

3.5.5.2.2 DME/N. The time delay shall be the interval between the time of the half voltage point on the leading edge of the second constituent interrogation pulse and the time at which the distance circuits reach the condition corresponding to zero distance indication.

3.5.5.2.3 DME/N. The time delay shall be the interval between the time of the half voltage point on the leading edge of the first constituent interrogation pulse and the time at which the distance circuits reach the condition corresponding to zero distance indication.

3.5.5.2.3 (Reserved) DME/P IA-Mode

3.5.5.2.3 (Reserved) DME/P FA-Mode

3.5.5.3 Receiver

3.5.5.3.1 Frequency of operation. The receiver center frequency shall be the transponder frequency appropriate to the assigned DME operating channel (see 3.5.3.3.3).

3.5.5.3.2 Receiver sensitivity

3.5.5.3.2.1 DME/N. The airborne equipment sensitivity shall be sufficient to acquire and provide distance information to the accuracy specified in 3.5.5.4 for the signal power density specified in 3.5.4.1.5.2.

Note. — Although the Standard in 3.5.5.3.2.1 is for DME/N interrogators, the receiver sensitivity is better than that necessary in order to operate with the power density of DME/N transponders given in 3.5.4.1.5.1 in order to assure interoperability with the IA mode of DME/P transponders.

3.5.5.3.2.2 (Reserved) DME/P Airborne equipment sensitivity

3.5.5.3.2.3 DME/N. The performance of the interrogator shall be maintained when the power density of the transponder signal at the interrogator antenna is between the minimum values given in 3.5.4.1.5 and a maximum of minus 18 dBW/m².

3.5.5.3.2.2 (Reserved) DME/P Performance of Interrogator

3.5.5.3.3 Bandwidth

3.5.5.3.3.1 DME/N. The receiver bandwidth shall be sufficient to allow compliance with 3.5.3.1.3, when the input signals are those specified in 3.5.4.1.3.

3.5.5.3.3.2 (Reserved) DME/P IA- Mode

3.5.5.3.3.3 (Reserved) DME/P FA- Mode

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 30

3.5.5.3.4 Interference rejection

3.5.5.3.4.1 When there is a ratio of desired to undesired co-channel DME signals of at least 8 dB at the input terminals of the airborne receiver, the interrogator shall display distance information and provide unambiguous identification from the stronger signal.

Note.— Co-channel refers to those reply signals that utilize the same frequency and the same pulse pair spacing.

3.5.5.3.4.2 DME/N. DME signals greater than 900 kHz removed from the desired channel nominal frequency and having amplitudes up to 42 dB above the threshold sensitivity shall be rejected.

3.5.5.3.4.3 (Reserved) DME/P DME Signals

3.5.5.3.5 Decoding

3.5.5.3.5.1 The interrogator shall include a decoding circuit such that the receiver can be triggered only by pairs of received pulses having pulse duration and pulse spacings appropriate to transponder signals as described in 3.5.4.1.4.

3.5.5.3.5.2 DME/N - Decoder rejection. A reply pulse pair with a spacing of plus or minus 2 microseconds, or more, from the nominal value and with any signal level up to 42 dB above the receiver sensitivity shall be rejected.

3.5.5.3.5.3 (Reserved) DME/P Decoder Rejection

3.5.5.4 Accuracy

3.5.5.4.1 DME/N. The interrogator shall not contribute more than plus or minus 315 m (plus or minus 0.17 NM) or 0.25 per cent of indicated range, whichever is greater, to the overall system error.

3.5.5.4.2 (Reserved) DME/P IA-Mode

3.5.5.4.3 (Reserved) DME/P FA-Mode

3.5.5.4.4 (Reserved) DME/P System Accuracy

3.6 (Reserved) Specification for en-route VHF marker beacons (75 MHz).

3.7 Requirements for the Global Navigation Satellite System (GNSS)

3.7.1 Definitions

Aircraft-based augmentation system (ABAS). An augmentation system that augments and/or integrates the information obtained from the other GNSS elements with information available on board the aircraft.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 31

Alert. An indication provided to other aircraft systems or annunciation to the pilot to identify that an operating parameter of a navigation system is out of tolerance.

Alert limit. For a given parameter measurement, the error tolerance not to be exceeded without issuing an alert.

Antenna port. A point where the received signal power is specified. For an active antenna, the antenna port is a fictitious point between the antenna elements and the antenna pre-amplifier. For a passive antenna, the antenna port is the output of the antenna itself.

Axial ratio. The ratio, expressed in decibels, between the maximum output power and the minimum output power of an antenna to an incident linearly polarized wave as the polarization orientation is varied over all directions perpendicular to the direction of propagation.

BeiDou Navigation Satellite System (BDS). The satellite navigation system operated by the People's Republic of China.

BDS Open Service (BDS OS). The specified level of positioning, velocity and timing accuracy that is available to any BDS user on a continuous, worldwide basis.

Channel of standard accuracy (CSA). The specified level of positioning, velocity and timing accuracy that is available to any GLONASS user on a continuous, worldwide basis.

Core satellite constellation(s). The core satellite constellations are GPS, and GLONASS, Galileo and BDS.

Galileo. The satellite navigation system operated by the European Union.

Galileo Open Service (Galileo OS). The specified level of positioning, velocity and timing accuracy that is available to any Galileo user on a continuous, worldwide basis.

Global navigation satellite system (GNSS). A worldwide position and time determination system that includes one or more satellite constellations, aircraft receivers and system integrity monitoring, augmented as necessary to support the required navigation performance for the intended operation.

Global navigation satellite system (GLONASS). The satellite navigation system operated by the Russian Federation.

Global positioning system (GPS). The satellite navigation system operated by the United States.

GNSS position error. The difference between the true position and the position determined by the GNSS receiver.

Ground-based augmentation system (GBAS). An augmentation system in which the user receives augmentation information directly from a ground-based transmitter.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 32

Ground-based regional augmentation system (GRAS). An augmentation system in which the user receives augmentation information directly from one of a group of ground-based transmitters covering a region.

Integrity. A measure of the trust that can be placed in the correctness of the information supplied by the total system. Integrity includes the ability of a system to provide timely and valid warnings to the user (alerts).

Ionosphere-free pseudo-range. A pseudo-range in which the first order ionosphere effect on signal propagation has been removed by a linear combination of pseudo-range measurements from signals on two distinct frequencies from the same satellite.

Pseudo-range. The difference between the time of transmission by a satellite and reception by a GNSS receiver multiplied by the speed of light in a vacuum, including bias due to the difference between a GNSS receiver and satellite time reference.

Satellite-based augmentation system (SBAS). A wide coverage augmentation system in which the user receives augmentation information from a satellite-based transmitter.

Standard positioning service (SPS). The specified level of positioning, velocity and timing accuracy that is available to any global positioning system (GPS) user on a continuous, worldwide basis.

Time-to-alert. The maximum allowable time elapsed from the onset of the navigation system being out of tolerance until the equipment enunciates the alert.

3.7.2 General

3.7.2.1 Functions

3.7.2.1.1 The GNSS shall provide position and time data to the aircraft.

Note - These data are derived from pseudo-range measurements between an aircraft equipped with a GNSS receiver and various signal sources on satellites or on the ground.

3.7.2.2 GNSS elements

3.7.2.2.1 The GNSS navigation service shall be provided using various combinations of the following elements installed on the ground, on satellites and/or on board the aircraft:

- a) Global Positioning System (GPS) that provides the Standard Positioning Service (SPS) as defined in 3.7.3.1.1;
- b) Global Navigation Satellite System (GLONASS) that provides the Channel of Standard Accuracy (CSA) as defined in 3.7.3.1.2;
- c) Galileo that provides a single- and dual-frequency Open Service (OS) as defined in 3.7.3.1.3;

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 33

- d) BeiDou Navigation Satellite System (BDS) that provides the BDS Open Service (BDS OS) as defined in 3.7.3.1.4;
- e) aircraft-based augmentation system (ABAS) as defined in 3.7.3.3;
- f) satellite-based augmentation system (SBAS) as defined in 3.7.3.4;
- g) ground-based augmentation system (GBAS) as defined in 3.7.3.5;
- h) ground-based regional augmentation system (GRAS) as defined in 3.7.3.5; and
- i) aircraft GNSS receiver as defined in 3.7.3.6.

Note.— In order to provide system integrity monitoring, the use of an augmentation as specified in 3.7.2.2.1 e), f), g) or h) is required to meet the performance requirements of 3.7.2.4.

3.7.2.3 Space and time reference

3.7.2.3.1 Space reference. The position information provided by the GNSS to the user shall be expressed in terms of the World Geodetic System -1984 (WGS-84) geodetic reference datum.

Note 1-SARPs for WGS-84 are contained in BCAR- 4, Chapter 2, BCAR- 11, Chapter 2, ICAO Annex 14, Volumes I and II, Chapter 1 and BCAR -15, Chapter 1.

Note 2- If GNSS elements using other than WGS-84 coordinates are employed, appropriate conversion parameters are to be applied. If the difference between a GNSS geodetic reference and WGS-84 is negligible for aviation (e.g. of the order of a few centimetres) and a bounding of the maximum difference is specified, then no conversion parameters need to be applied.

3.7.2.3.2 Time reference. The time data provided by the GNSS to the user shall be expressed in a time scale that takes the Universal Time Coordinated (UTC) as reference.

3.7.2.4 Signal-in-space performance

3.7.2.4.1 The combination of GNSS elements and a fault-free GNSS user receiver shall meet the signal-in-space requirements defined in Table 3.7.2.4-1 (located at the end of section 3.7).

Note 1 - The concept of a fault-free user receiver is applied only as a means of defining the performance of combinations of different GNSS elements. The fault-free receiver is assumed to be a receiver with nominal accuracy and time-to-alert performance. Such a receiver is assumed to have no failures that affect the integrity, availability and continuity performance.

Note 2.— For GBAS approach service (as defined in Attachment D, 7.1.2.1) intended to support approach and landing operations using Category III minima, performance requirements are defined that apply in addition to the signal-in-space requirements defined in Table 3.7.2.4.-1.

3.7.3 GNSS elements specifications

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

3.7.3.1 Core constellations

Note. — Unless otherwise specified, the performance standards in 3.7.3.1.1.1 to 3.7.3.1.1.7 below apply to single-frequency ranging, using the L1 coarse acquisition (C/A) code signal or the L5 signal (I5 code or Q5 code), and to dual-frequency ranging using the combination of L1 and L5 signals. In addition, they only apply to current and consistent ephemeris and clock data within the respective curve fit intervals.

3.7.3.1.1 GPS Standard Positioning Service (SPS) (L1, L5)

3.7.3.1.1.1 Space and control segment accuracy

Note. — The following accuracy standards apply only for healthy GPS SPS Signal-in-space (SIS) during normal operations as described in attachment D, 4.1.1.9 and do not include atmospheric or receiver errors as described in Attachment D, 4.1.1.2. GPS SPS SIS health conditions can be found in the United States Department of Defense, Global Positioning System – Standard Positioning Service – Performance Standard, 5th Edition, April 2020 (hereinafter referred to as “GPS SPS PS”), Section 2.3.2.

3.7.3.1.1.1.1 Positioning accuracy. The single frequency L1 C/A code position errors shall not exceed the following limits:

	Global average 95% of the time	Worst site 95% of the time
Horizontal position error	8 m	15 m
Vertical position error	13 m	33 m

3.7.3.1.1.1.2 Time transfer accuracy. The GPS SPS time transfer errors shall not exceed 30 nanoseconds 95 per cent of the time.

3.7.3.1.1.1.3 Range domain accuracy. The range domain error shall not exceed the following limits during normal operations over all ages of data:

- a) range error of any satellite — 30 m with reliability specified in 3.7.3.1.1.3;
- b) 95th percentile range rate error of any satellite — 0.006 m per second (global average);
- c) 95th percentile range acceleration error of any satellite — 0.002 m per second-squared (global average); and
- d) 95th percentile range error for any satellite 7.0 m (global average); and
- e) 95th percentile range error across all satellites occupying defined slots in the constellation — 2.0 m (global average).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 35

3.7.3.1.1.2 Availability. The availability for single-frequency L1 C/A code users shall be as follows:

- ≥99 per cent horizontal service availability, average location (15 m 95 per cent threshold)
- ≥99 per cent vertical service availability, average location (33 m 95 per cent threshold)
- ≥90 per cent horizontal service availability, worst-case location (15 m 95 per cent threshold)
- ≥90 per cent vertical service availability, worst-case location (33 m 95 per cent threshold)

3.7.3.1.1.3 Reliability. The GPS SPS reliability relative to the 30 m user range error (URE) statistic in 3.7.3.1.1.1.3 a) shall be within the following limits:

- a) reliability — at least 99.94 per cent (global average); and
- b) reliability — at least 99.79 per cent (worst single point average).

3.7.3.1.1.4 Probability of major service failure.

Note. — *The different alert indications are described in the GPS SPS PS, Section 2.3.4.*

3.7.3.1.1.4.1 *Satellite major service failure onset rate (R_{sat}).* The probability that the instantaneous user range error (URE) of any satellite will exceed 4.42 times the relevant integrity assured user range accuracy (IAURA) value broadcast by that satellite without an alert received at the user receiver antenna within 10 seconds shall not exceed 1×10^{-5} per hour.

3.7.3.1.1.4.2 *Probability of a satellite major service failure condition (P_{sat}).* The probability at any given instant that the instantaneous URE of any satellite will exceed 4.42 times the relevant IAURA value broadcast by that satellite without an alert received at the user receiver antenna within 10 seconds shall not exceed 1×10^{-5} .

3.7.3.1.1.4.3 *Probability of a common-cause major service failure condition (P_{const}).* The probability at any given instant that the instantaneous URE of two or more satellites will exceed 4.42 times the relevant IAURA broadcast by each satellite due to a common fault without an alert received at the user receiver antenna within 10 seconds shall not exceed 1×10^{-8} .

3.7.3.1.1.5 Continuity. The probability of losing L1 C/A availability from a slot of the 24-slot constellation due to unscheduled interruption shall not exceed 2×10^{-4} per hour.

3.7.3.1.1.6 Coverage. The GPS SPS shall cover the surface of the earth up to an altitude of 3 000 kilometers.

Note. — *Guidance material on GPS accuracy, availability, reliability, major service failure, continuity, and coverage is given in Attachment D, 4.1.1. Additional information is given in the GPS SPS PS.*

3.7.3.1.1.7 *Constellation availability.* The probability that 21 or more of the 24 slots will be occupied by either a satellite broadcasting a trackable and healthy L1 C/A signal in the baseline slot configuration or by a pair of satellites each broadcasting a trackable and healthy L1 C/A signal in the expanded slot

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 36

configurations, shall be at least 0.98. The probability that 20 or more of the 24 slots will be occupied by either a satellite broadcasting a trackable and healthy L1 C/A signal in the baseline slot configuration or by a pair of satellites each broadcasting a trackable and healthy L1 C/A signal in the expanded slot configurations, shall be at least 0.99999.

Note. — There is currently no corresponding standard for the L5 signal or for the combined L1 C/A and L5 signals since older satellites in the constellation do not have the capability to broadcast an L5 signal.

3.7.3.1.1.8 Radio frequency (RF) characteristics

Note. — Detailed RF characteristics are specified in NAVSTAR GPS Space Segment/Navigation User Segment Interfaces, IS No. IS-GPS-200, Rev K (hereinafter referred to as “IS-GPS-200K”) for L1 and NAVSTAR GPS Space Segment/User Segment L5 Interfaces, IS No. IS-GPS-705, Rev F (hereinafter referred to as “IS-GPS-705F”); selected characteristics are specified in Appendix B, 3.1.1.1.1 for L1 and Appendix B, 3.1.1.1.4 for L5.

3.7.3.1.1.8.1 *L1 carrier frequency.* Each GPS satellite shall broadcast an SPS ranging signal at the carrier frequency of 1 575.42 MHz (GPS L1) using code division multiple access (CDMA).

3.7.3.1.1.8.2 *L5 carrier frequency.* Some GPS satellites shall, in addition, broadcast an SPS ranging signal at the carrier frequency of 1 176.45 MHz (GPS L5) using CDMA.

3.7.3.1.1.8.3 *Signal spectrum.* The L1 and L5 signal power shall be contained within a ± 12 MHz bands centred on the respective carrier frequencies: (1 563.42 – 1 587.42 MHz) for L1. and 1 164.45 – 1 188.45 for L5.

3.7.3.1.1.8.4 *Polarization.* The transmitted L1 and L5 RF signals shall be right-hand circularly polarized.

3.7.3.1.1.8.5 *Signal structure.* The L1 C/A signal shall consist of one carrier component. The L5 signal shall consist of two carrier components: an in-phase component (I5) and a quadrature component lagging the in-phase component by 90 degrees (Q5).

3.7.3.1.1.8.6 *Signal power level.* Each GPS satellite shall broadcast SPS navigation signals with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly -polarized antenna is within the following ranges for all antenna orientations orthogonal to the direction of propagation: –158.5 dBW to –153 dBW for L1 C/A and –157.9 dBW to –150 dBW for each of the I5 and Q5 channels on L5.

3.7.3.1.1.8.7 *Modulation.* Each SPS L1 and L5 signal shall be bipolar phase shift key (BPSK) modulated with a pseudo random noise (PRN) code. The C/A code on L1 shall have a rate of 1.023 megachips per second. The codes on I5 and Q5 shall have a rate of 10.23 megachips per second.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 37

3.7.3.1.1.8.7.1 The C/A, I5, and Q5 code sequences shall be repeated each millisecond.

3.7.3.1.1.8.7.2 The transmitted code sequence on L1 shall be the Modulo-2 addition of a 50-bit-per-second legacy navigation (LNAV) message and the C/A code.

3.7.3.1.1.8.7.3 The transmitted code sequence on I5 shall be the Modulo-2 addition of a 50-bit-per-second civil navigation (CNAV) message (rate 1/2 convolution encoded into a 100 symbol per second stream), a 10-bit Neuman-Hofman overlay code clocked at 1 kbps, and the I5 code. The transmitted code sequence on Q5 shall be the Modulo-2 addition of a 20-bit Neuman-Hofman overlay code clocked at 1 kbps and the Q5 code.

Note. — *The Q5 signal is not modulated with navigation data.*

3.7.3.1.1.8.7.4 *Signal coherence.* All transmitted signals for any satellite shall be coherently derived from the same on-board frequency standard. On the L5 channel, the chip transitions of the two modulating signals, I5 and Q5, shall be such that the average time difference between them does not exceed 10 nanoseconds.

3.7.3.1.1.9 GPS time. GPS time shall be referenced to UTC (as maintained by the U.S. Naval Observatory).

3.7.3.1.1.10 Coordinate system. The GPS coordinate system shall be WGS-84.

3.7.3.1.1.11 Navigation information. The navigation data transmitted by the satellites on L1 and L5 shall include the necessary information to determine:

1. satellite time of transmission;
2. satellite position;
3. satellite health;
4. satellite clock correction;
5. propagation delay effects;
6. time transfer to UTC; and
7. constellation status.

Note- Structure and contents of data are specified in Appendix B, 3.1.1.1.2 and 3.1.1.1.3 for L1, and 3.1.1.1.5 and 3.1.1.1.6 for L5.

3.7.3.1.2 GLONASS Channel of Standard Accuracy (CSA) (L1/L3)

Note. — *The GLONASS signals for CSA are broadcast in two frequency bands identified as L1 and L3. In the L1 band, two types of signals are broadcast: L1OF with frequency division multiple access (FDMA) and L1OC with code division multiple access (CDMA). In the L3 band, only CDMA signals (L3OC) are broadcast. Except where otherwise specified, the term GLONASS refers to all satellites in the constellation transmitting either FDMA or CDMA signals.*

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

3.7.3.1.2.1 Space and control segment accuracy

Note. — *The Single-Frequency accuracy Standards do not include atmospheric or receiver errors; ionosphere errors are included for dual-frequency combinations, as described in Attachment D, 4.1.2.2.*

3.7.3.1.2.1.1 Positioning accuracy. The GLONASS CSA position errors shall not exceed the following limits:

Signals	L1OF	L1OC	L3OC	L1OF - L3OC	L1OC - L3OC
Global average					
95% of the time:					
Horizontal position error	5 m	5 m	5 m	5 m	5 m
Vertical position error	9 m	9 m	9 m	9 m	9 m
Worst site					
95% of the time:					
Horizontal position error	12 m	12 m	12 m	12 m	12 m
Vertical position error	25 m	25 m	25 m	25 m	25 m

3.7.3.1.2.1.2 Time transfer accuracy. The GLONASS CSA time transfer errors shall not exceed the following limits 95 per cent of the time.

Signals	L1OF	L1OC	L3OC	L1OF - L3OC	L1OC - L3OC
	40 ns	40 ns	40 ns	40 ns	40 ns

3.7.3.1.2.1.3 Range domain accuracy. The range domain error shall not exceed the following limits:

Signals	L1OF	L1OC	L3OC	L1OF - L3OC	L1OC - L3OC
Range error of any satellite with reliability specified in 3.7.3.1.2.3	18 m	18 m	18 m	18 m	18 m
95th percentile range error of any satellite	11.7 m	11.7 m	11.7 m	11.7 m	11.7 m
95th percentile range error over all satellites	7.8 m	7.8 m	7.8 m	7.8 m	7.8 m
95th percentile range rate error of any satellite	0.014 m/s	0.014 m/s	0.014 m/s	0.014 m/s	0.014 m/s
95th percentile range acceleration error of any satellite	0.005 m/s ²	0.005 m/s ²	0.005 m/s ²	0.005 m/s ²	0.005 m/s ²

3.7.3.1.2.2 Availability. The GLONASS CSA availability shall be as follows:

Signals	L1OF	L1OC	L3OC	L1OF - L3OC	L1OC - L3OC
Average location:					
Horizontal service availability	99%, (12 m 95% threshold)	99%, (12 m 95% threshold)	99%, (12 m 95% threshold)	99%, (12 m 95% threshold)	99%, (12 m 95% threshold)
Vertical service availability	99%, (25 m 95% threshold)	99%, (25 m 95% threshold)	99%, (25 m 95% threshold)	99%, (25 m 95% threshold)	99%, (25 m 95% threshold)
Worst-case location:					
Horizontal service availability	90%, (12 m 95% threshold)	90%, (12 m 95% threshold)	90%, (12 m 95% threshold)	90%, (12 m 95% threshold)	90%, (12 m 95% threshold)
Vertical service availability	90%, (25 m 95% threshold)	90%, (25 m 95% threshold)	90%, (25 m 95% threshold)	90%, (25 m 95% threshold)	90%, (25 m 95% threshold)

3.7.3.1.2.3 Reliability. The GLONASS CSA reliability shall be within the following limits:

Signals	L1OF	L1OC	L3OC	L1OF – L3OC	L1OC – L3OC
Global average	99.37%	99.37%	99.37%	99.37%	99.37%
Worst single point average	99.14%	99.14%	99.14%	99.14%	99.14%

3.7.3.1.2.4 *Probability of major service failure.* The probability that the user range error (URE) of any satellite will exceed the following tolerance without an alert received at the user receiver antenna within 10 seconds shall not exceed the following probability:

Signals	L1OF	L1OC	L3OC	L1OF – L3OC	L1OC – L3OC
Single satellite failure (P_{sat})	1×10^{-4} , (70 m threshold)	1×10^{-4} , (70 m threshold)	1×10^{-4} , (70 m threshold)	1×10^{-4} , (70 m threshold)	1×10^{-4} , (70 m threshold)

3.7.3.1.2.5 *Probability of constellation fault.* The probability that the user range error (URE) of more than one satellite will exceed the following tolerance simultaneously without an alert received at the user receiver antenna within 10 seconds shall not exceed the following probability:

Signals	L1OF	L1OC	L3OC	L1OF – L3OC	L1OC – L3OC
Constellation fault (P_{const})	1×10^{-4} , (70 m threshold)	1×10^{-4} , (70 m threshold)	1×10^{-4} , (70 m threshold)	1×10^{-4} , (70 m threshold)	1×10^{-4} , (70 m threshold)

3.7.3.1.2.6 *Continuity*. The probability of losing GLONASS CSA healthy signal availability from a slot of the nominal 24-slot constellation due to unscheduled interruption shall not exceed the following limit:

3.7.3.1.2. 7 Coverage. The GLONASS CSA shall cover the surface of the earth up to an altitude of 2 000 km.

Note - Guidance material on GLONASS accuracy, availability, reliability and coverage is given in Attachment D, 4.1.2.

3.7.3.1.2. 8 L1OF RF characteristics

Note - Detailed RF characteristics are specified in Appendix B, 3.1.2.1.1.

3.7.3.1.2. 8.1 Carrier frequency. Each GLONASS satellite shall broadcast CSA navigation signal at its own carrier frequency in the L1 (1.6 GHz) frequency band using frequency division multiple access (FDMA).

Note - GLONASS satellites may have the same carrier frequency but in this case they are located in antipodal slots of the same orbital plane.

Note 2 - GLONASS-M satellites will broadcast an additional ranging code at carrier frequencies in the L2 (1.2 GHz) frequency band using FDMA.

3.7.3.1.2. 8.2 Signal spectrum. GLONASS CSA signal power shall be contained within a ± 5.75 MHz band centered on each GLONASS carrier frequency.

3.7.3.1.2. 8.3 Polarization. The transmitted RF signal shall be right-hand circularly polarized.

3.7.3.1.2.8.4 Signal power level. Each GLONASS satellite shall broadcast CSA navigation signals with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly polarized antenna is within the range of -161 dBW to -155.2 dBW for all antenna orientations orthogonal to the direction of propagation.

Note 1. — The power limit of 155.2 dBW is based on the predetermined characteristics of a user antenna, atmospheric losses of 0.5 dB and an error of an angular position of a satellite that does not exceed one degree (in the direction causing the signal level to increase).

Note 2. — GLONASS-M satellites will also broadcast a ranging code on L2 with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 41

degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly polarized antenna is not less than -167 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.1.2.8.5 Modulation

3.7.3.1.2.8.5.1 Each GLONASS satellite shall transmit at its carrier frequency the navigation RF signal using a BPSK-modulated binary train. The phase shift keying of the carrier shall be performed at π -radians with the maximum error ± 0.2 radian. The pseudo-random code sequence shall be repeated each millisecond.

3.7.3.1.2.8.5.2 The modulating navigation signal shall be generated by the Modulo-2 addition of the following three binary signals:

- a) ranging code transmitted at 511 kbits/s;
- b) navigation message transmitted at 50 bits/s; and
- c) 100 Hz auxiliary meander sequence.

3.7.3.1.2.9 L3OC RF characteristics

Note. — Detailed RF characteristics are specified in Appendix B, 3.1.2.1.5.

3.7.3.1.2.9.1 *Carrier frequency.* GLONASS L3OC navigation signals shall be broadcast at the carrier frequency of 1 202.025 MHz using code division multiple access (CDMA).

3.7.3.1.2.9.2 *Signal spectrum.* GLONASS CSA L3OC signal power shall be contained within the 1 190.35 – 1 212.23 MHz band.

3.7.3.1.2.9.3 *Polarization.* The transmitted L3OC signal shall be right-hand circularly polarized.

3.7.3.1.2.9.4 *Signal power level.* GLONASS L3OC navigation signals shall be broadcast with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly polarized antenna is within the range of -158.5 dBW to -155.2 dBW for all antenna orientations orthogonal to the direction of propagation.

Note. — The power limit of 155.2 dBW is based on the predetermined characteristics of a user antenna, atmospheric losses of 0.5 dB and an error of an angular position of a satellite that does not exceed one degree (in the direction causing the signal level to increase).

3.7.3.1.2.9.5 Modulation

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 42

Note. — Additional information concerning the modulation is given in the *GLONASS CDMA ICD Open Service Navigation Signal in L3 frequency band (Edition 1.0)*, dated 2016 (hereinafter referred to as “*GLONASS CDMA ICD L3 band*”).

3.7.3.1.2.9.5.1 GLONASS L3OC navigation signals shall contain two components using the same BPSK (10)-modulated binary train: an in-phase data component and a quadrature-phase pilot component identified as L3OCd and L3OCp, respectively. The pilot component leads the data component by $\pi/2$ radians.

3.7.3.1.2.9.5.2 The L3OCd signal component shall be generated by the Modulo-2 addition of the following three binary signals:

- a) ranging code with length $N=10230$, period $T=1$ ms, clock rate 10.23 MHz;
- b) 100 bits/s navigation message encoded using a convolutional encoder with constraint length 7 and code rate $1/2$ to yield 200 symbols per second; and
- c) overlay code “00010” with period $T=5$ ms.

3.7.3.1.2.9.5.3 The L3OCp signal component shall be generated by the Modulo-2 addition of the following two binary signals:

- a) ranging code with length $N=10230$, period $T=1$ ms, clock rate 10.23 MHz; and
- b) overlay code “0000110101” with period $T=10$ ms.

3.7.3.1.2.10 L1OC RF characteristics

Note. — Detailed RF characteristics are specified in Appendix B, 3.1.2.1.5.

3.7.3.1.2.10.1 *Carrier frequency.* GLONASS L1OC navigation signals shall be broadcast at the carrier frequency of 1600.995 MHz using code division multiple access (CDMA).

3.7.3.1.2.10.2 *Signal spectrum.* GLONASS CSA L1OC signal power shall be contained within the 1 592.9 – 1 610 MHz band.

3.7.3.1.2.10.3 *Polarization.* The transmitted L1OC signal shall be right-hand circularly polarized.

3.7.3.1.2.10.4 *Signal power level.* GLONASS L1OC navigation signals shall be broadcast with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly polarized antenna is within the range of -158.5 dBW to -155.2 dBW for all antenna orientations orthogonal to the direction of propagation.

Note. — The power limit of -155.2 dBW is based on the predetermined characteristics of a user antenna, atmospheric losses of 0.5 dB and an error of an angular position of a satellite that does not exceed one degree (in the direction causing the signal level to increase).

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 43

3.7.3.1.2.10.5 Modulation

Note. — Additional information concerning the modulation is given in the GLONASS CDMA ICD Open Service Navigation Signal in L1 frequency band (Edition 1.0), dated 2016 (hereinafter referred to as “GLONASS CDMA ICD L1 band”).

3.7.3.1.2.10.5.1 GLONASS L1OC navigation signals shall contain two components: a data component and a pilot component identified as L1OCd and L1OCp, respectively. Both components shall be at one phase quadrature using time-division multiplexing. L1OCd shall be modulated using binary phase-shift keying BPSK (1), while L1OCp shall be modulated by binary offset carrier BOC(1,1) modulation.

3.7.3.1.2.10.5.2 The L1OCd signal component shall be generated by the Modulo-2 addition of the following three binary signals:

- a) ranging code with length $N=1023$, period $T=2$ ms, clock rate 0.5115 MHz;
- b) 125 bits/s navigation message encoded using a convolutional encoder with constraint length 7 and code rate 1/2 to yield 250 symbols per second; and
- c) overlay code “01” with period $T=4$ ms.

3.7.3.1.2.10.5.3 The L1OCp signal component shall be generated by the Modulo-2 addition of the following two binary signals:

- a) ranging code with length $N=4092$, period $T=8$ ms, clock rate 0.5115 MHz; and
- b) meander sequence “0101” with clock rate 2.046 MHz.

3.7.3.1.2.11 GLONASS time. GLONASS time shall be referenced to UTC(SU) (as maintained by the National Time Service of Russia).

3.7.3.1.2. 12 Coordinate system. The GLONASS coordinate system shall be PZ-90.

Note - Conversion from the PZ-90 coordinate system used by GLONASS to the WGS-84 coordinates is defined in Appendix B, 3.2.5.2.

3.7.3.1.2.13 Navigation information. The navigation data transmitted by the satellite shall include the necessary information to determine:

- a) satellite time of transmission;
- b) satellite position;
- c) satellite health;

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 44

- d) satellite clock correction;
- e) time transfer to UTC; ~~and~~
- f) constellation status;
- g) ionospheric delay effects (L1OC, L3OC only); and
- h) satellite orientation in umbra (L1OC, L3OC only).

Note. — Structure and contents of data are specified in Appendix B, 3.1.2.1.2 and 3.1.2.1.3, respectively.

3.7.3.1.3 Galileo Open Service (Galileo OS) (E1, E5)

Note 1.— The Galileo signals for Galileo OS are broadcast in two frequency bands identified as E1 and E5. In the E5 band, two types of signals are broadcast with code division multiple access (CDMA): E5a and E5b. For aviation purposes, the Galileo single-frequency OS is based on either E1 or E5a signals; and the Galileo dual-frequency OS is based on a combination of E1 and E5a signals.

Note 2.— The E5b signal component is described in this Annex since it is a subset of the overall Galileo signal modulated on the E5 frequency carrier. However, there is currently no intention that the E5b signal be used by aviation receivers.

Note 3. — The following performance standards only apply if “healthy” signals-in-space are used (see Appendix B, 3.1.3.1.3.4).

Note 4. — The following performance standards do not include atmospheric or receiver errors such as ionosphere, troposphere, interference, receiver noise or multipath.

Note 5. — Guidance material on Galileo OS accuracy, availability, continuity, probability of satellite/constellation failure and coverage, is given in Attachment D, 4.1.3.

3.7.3.1.3.1 Positioning accuracy. The Galileo position errors shall not exceed the following limits:

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 45

Signals	E1	E5a	E1-E5a
Global average 95% of the time:			
Horizontal position error over a measurement period of 30 days	5 m	5 m	5 m
Vertical position error over a measurement period of 30 days	8 m	8 m	8 m
Worst site 95% of the time:			
Horizontal position error over a measurement period of 30 days	10 m	10 m	10 m
Vertical position error over a measurement period of 30 days	16 m	16 m	16 m

3.7.3.1.3.2 *Time determination accuracy.* The Galileo UTC time determination error shall not exceed 30 nanoseconds, 95 per cent of the time.

3.7.3.1.3.3 *Range domain accuracy.* The Galileo range domain error shall not exceed the following limits:

Signals	E1	E5a	E1-E5a
99.9th percentile range error of any satellite (worst-case location)	20 m	20 m	20 m
99.9th percentile range error of any satellite (global average)	10 m	10 m	10 m
95th percentile range error of any satellite (global average)	7 m	7 m	7 m
95th percentile range error over all satellites (global average)	2 m	2 m	2 m
95th percentile range rate error of any satellite (global average)	5 mm/s	5 mm/s	5 mm/s

Note 1.— The ranging accuracy considers only healthy Galileo OS SIS above a minimum elevation angle of 5 degrees.

Note 2.— Single-frequency (E1 or E5a) ranging accuracy includes broadcast group delay (BGD) errors. BGD definition is specified in Attachment D, 4.1.3.3.2.

3.7.3.1.3.4 *Availability.* The Galileo OS availability shall be as follows:

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

Signals	E1	E5a	E1-E5a
Average location:			
Horizontal service availability over a measurement period of 30 days	99% (10 m 95% threshold)	99% (10 m 95% threshold)	99% (10 m 95% threshold)
Vertical service availability over a measurement period of 30 days	99% (16 m 95% threshold)	99% (16 m 95% threshold)	99% (16 m 95% threshold)
Worst-case location:			
Horizontal service availability over a measurement period of 30 days	90% (10 m 95% threshold)	90% (10 m 95% threshold)	90% (10 m 95% threshold)
Vertical service availability over a measurement period of 30 days	90% (16 m 95% threshold)	90% (16 m 95% threshold)	90% (16 m 95% threshold)

3.7.3.1.3.5 *Probability of satellite failure (P_{sat})*. The probability that one satellite of Galileo operational core constellation provides an instantaneous SIS range error higher than k times the Galileo user range accuracy (Galileo URA) and no notification is given to the user, shall not exceed 3×10^{-5} .

Note 1. — A change in the SIS health status is notified through the flags contained in the navigation message. The mapping between Galileo SIS status and flags contained in the navigation data message is specified in Appendix B, 3.1.3.1.3.4. In the future, these flags may be complemented with an additional flag specific for aircraft-based augmentation system (ABAS) users.

Note 2. — Galileo URA corresponds either to $\sigma_{URA,DF}$ for dual-frequency users or to $\sigma_{URA,SF}$ for single-frequency users.

Note 3. — P_{sat} definition is further specified in Attachment D, 4.1.3.6.1.

3.7.3.1.3.6 *Probability of constellation failure (P_{const})*. The probability that, due to a common cause, any subset of two or more satellites within Galileo operational constellation provides an instantaneous SIS range error higher than k times the Galileo URA and no notification is given to the user, shall not exceed 2×10^{-4} .

Note 1. — A change in the SIS health status is notified through the flags contained in the navigation message. The mapping between Galileo SIS status and flags contained in the navigation data message is specified in Appendix B, 3.1.3.1.3.4. In the future, these flags may be complemented with an additional flag specific for ABAS users.

Note 2. — Galileo URA corresponds either to $\sigma_{URA,DF}$ for dual-frequency users or to $\sigma_{URA,SF}$ for single-frequency users.

Note 3. — P_{const} definition is further specified in Attachment D, 4.1.3.6.2.

3.7.3.1.3.7 *Galileo URA for dual-frequency ($\sigma_{URA,DF}$)*. Galileo $\sigma_{URA,DF}$ shall not exceed 6 m.

	Aeronautical telecommunication Volume - I		BCAR-10	
	Specification for radio navigation aids		Chapter: 3	Page: 47

Note 1.— $\sigma_{URA,DF}$ applies to a dual-frequency E1-E5a signal combination.

Note 2. — $\sigma_{URA,DF}$ is defined in Attachment D, 4.1.3.6.3.

3.7.3.1.3.8 Galileo URA for single-frequency ($\sigma_{URA,SF}$). Galileo $\sigma_{URA,SF}$ shall not exceed 7.5 m.

Note 1.— $\sigma_{URA,SF}$ applies to a single-frequency user, either E1 or E5a.

Note 2. — $\sigma_{URA,SF}$ is defined in Attachment D, 4.1.3.6.4.

3.7.3.1.3.9 Continuity. The probability of losing Galileo OS SIS availability from a slot of the nominal 24-slot constellation due to unscheduled interruption, shall not exceed the following limit:

Signals	E1	E5a	E1-E5a
Continuity	4×10^{-4} per hour	4×10^{-4} per hour	4×10^{-4} per hour

3.7.3.1.3.10 Coverage. The Galileo OS shall cover the surface of the earth up to an altitude of 30.48 km.

3.7.3.1.3.11 Radio frequency (RF) characteristics. All Galileo satellites shall broadcast Galileo OS signals E1, E5a and E5b.

Note 1.— E5a and E5b signals are multiplexed together through an AltBOC scheme and transmitted at the E5 carrier frequency centred at 1191.795 MHz. AltBOC modulation allows E5a signal components and E5b signal components to be recovered separately by using a QPSK receiver centred on the individual E5a and E5b frequencies.

Note 2. — AltBOC modulation is specified in Appendix B, 3.1.3.1.1.3.13.

Note 3. — Detailed Galileo signals RF characteristics are specified in Appendix B, 3.1.3.1.1.

3.7.3.1.3.11.1 E1 radio frequency (RF) characteristics

3.7.3.1.3.11.1.1 E1 carrier frequency. Each Galileo satellite shall broadcast E1 signal at the carrier frequency of 1575.420 MHz using CDMA.

3.7.3.1.3.11.1.2 E1 signal spectrum. The Galileo signal power on E1 shall be contained within a 24.552 MHz band centred on the E1 frequency.

3.7.3.1.3.11.1.3 E1 signal polarization. The transmitted E1 RF signal shall be right-hand circularly polarized.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 48

3.7.3.1.3.11.1.4 *E1 minimum signal power level.* Each Galileo satellite shall broadcast an E1 navigation signal with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna shall not be less than -157.9 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.1.3.11.1.5 *E1 maximum signal power level.* Each Galileo satellite shall broadcast an E1 navigation signal such that the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna shall not exceed -151.45 dBW.

3.7.3.1.3.11.1.6 *E1 signal modulation.* The E1 signal shall be a composite binary offset carrier (CBOC) generated by multiplexing a wideband binary offset carrier (BOC) signal BOC(6,1) with a narrowband signal BOC(1,1) in such a way that 1/11 of the power is allocated, in average, to the high frequency component.

Note. — CBOC modulation is specified in Appendix B, 3.1.3.1.1.2.7.

3.7.3.1.3.11.2 *E5a radio frequency (RF) characteristics*

Note. — Additional information concerning the overall E5 signal modulation is given in the European GNSS (Galileo) Open Service Signal-In-Space Interface Control Document (Issue 2.0), dated January 2021 (hereinafter referred to as “Galileo OS SIS ICD”).

3.7.3.1.3.11.2.1 *E5a carrier frequency.* Each Galileo satellite shall broadcast E5a signal at the carrier frequency of 1 176.45 MHz using CDMA.

3.7.3.1.3.11.2.2 *E5a signal spectrum.* The Galileo signal power on E5a shall be contained within a 20.460 MHz band centred on the E5a frequency.

3.7.3.1.3.11.2.3 *E5a signal polarization.* The transmitted E5a RF signal shall be right-hand circularly polarized.

3.7.3.1.3.11.2.4 *E5a minimum signal power level.* Each Galileo satellite shall broadcast an E5a navigation signal with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna shall not be less than -155.90 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.1.3.11.2.5 *E5a maximum signal power level.* Each Galileo satellite shall broadcast an E5a navigation signal such that the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna shall not exceed -149.45 dBW.

3.7.3.1.3.11.2.6 *E5a signal modulation.* The E5a signal shall be generated from Modulo-2 addition of the E5a navigation data stream with the 10.23 megachips per second E5a data channel ranging code (E5a-I), and the 10.23 megachips per second E5a pilot channel ranging code (E5a-Q).

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 49

3.7.3.1.3.11.3 *E5b radio frequency (RF) characteristics*

Note. — Additional information concerning the overall E5 signal modulation is given in Galileo OS SIS ICD.

3.7.3.1.3.11.3.1 *E5b carrier frequency.* Each Galileo satellite shall broadcast E5b signal at the carrier frequency of 1207.14 MHz using CDMA.

3.7.3.1.3.11.3.2 *E5b signal spectrum.* The Galileo signal power on E5b shall be contained within a 20.460 MHz band centred on the E5b frequency.

3.7.3.1.3.11.3.3 *E5b signal polarization.* The transmitted E5b RF signal shall be right-hand circularly polarized.

3.7.3.1.3.11.3.4 *E5b minimum signal power level.* Each Galileo satellite shall broadcast an E5b navigation signal with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna shall not be less than -155.90 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.1.3.11.3.5 *E5b maximum signal power level.* Each Galileo satellite shall broadcast an E5b navigation signal such that the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna shall not exceed -149.45 dBW.

3.7.3.1.3.11.3.6 *E5b signal modulation.* The E5b signal shall be generated from Modulo-2 addition of the E5b navigation data stream with the 10.23 megachips per second E5b data channel ranging code (E5b-I), and the 10.23 megachips per second E5b pilot channel ranging code (E5b-Q).

3.7.3.1.3.12 *Galileo system time.* Galileo system time (GST) shall be referenced to UTC BIPM (UTC as coordinated by the International Bureau of Weights and Measures).

Note. — Further details on GST are specified in Appendix B, 3.1.3.4.1.

3.7.3.1.3.13 *Coordinate system.* The Galileo coordinate system shall be Galileo Terrestrial Reference Frame (GTRF).

Note. — GTRF details are specified in Appendix B, 3.1.3.5.2.

3.7.3.1.3.14 *Navigation information.* The navigation data transmitted by the satellites shall include the necessary information to determine:

- a) satellite time of transmission;
- b) satellite position;
- c) satellite health;
- d) satellite clock correction;
- e) ionospheric delay effects;
- f) time transfer to UTC; and
- g) constellation status.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 50

Note. — Structure and contents of data are specified in Appendix B, 3.1.3.1.2 and 3.1.3.1.2, respectively.

3.7.3.1.4 BDS Open Service (BDS OS) (B1I, B1C, B2a)

Note 1.— The BDS OS signals are broadcast in three frequency bands identified as B1I, B1C and B2a. The single-frequency BDS OS is based on any one of the B1I, B1C or B2a signals. The dual-frequency BDS OS is based on a combination of the B1C and B2a signals.

Note 2.— BDS OS signals B1I, B1C and B2a are broadcast by all BDS-3 (BDS third-phase) medium earth orbit (MEO) and inclined geosynchronous orbit (IGSO) satellites.

Note 3.— All requirements specified in this section are based on the BDS-3 constellation configuration of 24 MEO and 3 IGSO satellites.

3.7.3.1.4.1 Space and control segment accuracy

Note. — The following accuracy standards do not include atmospheric or receiver errors as described in Attachment D, 4.1.4.2. They only apply under the condition that the aircraft receiver uses healthy satellites.

3.7.3.1.4.1.1 *Positioning accuracy.* The BDS position errors shall not exceed the following limits:

Signals	B1I	B1C	B2a	B1C-B2a
Global average 95% threshold:				
Horizontal position over a measurement period of 7 days	9 m	9 m	9 m	9 m
Vertical position error over a measurement period of 7 days	15 m	15 m	15 m	15 m
Worst site 95% threshold:				
Horizontal position error over a measurement period of 7 days	15 m	15 m	15 m	15 m
Vertical position error over a measurement period of 7 days	22 m	22 m	22 m	22 m

3.7.3.1.4.1.2 *Time transfer accuracy.* The BDS OS time transfer error shall not exceed 50 nanoseconds, 95 per cent of the time.

3.7.3.1.4.1.3 *Range domain accuracy.* The BDS range domain error shall not exceed the following limits:

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

Signals	B1I	B1C	B2a	B1C- B2a
Range error of any satellite with reliability specified in 3.7.3.1.4.3	15 m	15 m	15 m	15 m
95th percentile error of any satellite over a measurement period of 7 days (global average)	4.6 m	4.6 m	4.6 m	4.6 m
95th percentile range rate error of any satellite (global average)	0.02 m per second	0.02 m per second	0.02 m per second	0.02 m per second
95th percentile range acceleration error of any satellite (global average)	0.008 m per second squared	0.008 m per second squared	0.008 m per second squared	0.008 m per second squared

3.7.3.1.4.2 *Availability*. The BDS OS availability shall be as follows:

Signals	B1I	B1C	B2a	B1C- B2a
<i>Average location:</i>				
Horizontal service availability over a measurement period of 7 days	≥ 99% (15 m 95% threshold)	≥ 90% (15 m 95% threshold)	≥ 99% (15 m 95% threshold)	≥ 99% (15 m 95% threshold)
Vertical service availability over a measurement period of 7 days	≥ 99% (22 m 95% threshold)	≥ 90% (22 m 95% threshold)	≥ 99% (22 m 95% threshold)	≥ 99% (22 m 95% threshold)
<i>Worst-case location:</i>				
Horizontal service availability over a measurement period of 7 days	≥ 90% (15 m 95% threshold)	≥ 90% (15 m 95% threshold)	≥ 90% (15 m 95% threshold)	≥ 90% (15 m 95% threshold)
Vertical service availability over a measurement period of 7 days	≥ 90% (22 m 95% threshold)	≥ 90% (22 m 95% threshold)	≥ 90% (22 m 95% threshold)	≥ 90% (22 m 95% threshold)

Note. — Availability applies under the condition that the aircraft receiver uses healthy satellites.

3.7.3.1.4.3 *Reliability*. The BDS OS reliability relative to the 15 m range error requirement in 3.7.3.1.4.2 shall be within the following limits:

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 52

- a) reliability — at least 99.94 per cent (global average); and
- b) reliability — at least 99.79 per cent (worst single point average).

Note. — Reliability applies under the condition that the satellite is broadcasting a healthy indication.

3.7.3.1.4.4 Probability of major service failure

Note. — The standards apply under the condition that the satellite is broadcasting a healthy indication.

3.7.3.1.4.4.1 *Probability of a satellite major service failure condition (P_{sat}).* The probability that the BDS OS SIS user range error of any satellite will exceed the not-to-exceed (NTE) tolerance without an alert received at the user receiver antenna within 300 seconds, shall not exceed 1×10^{-5} .

3.7.3.1.4.4.2 *Probability of a common-cause major service failure condition (P_{const}).* The probability that the BDS OS SIS user range error of two or more satellites will exceed the NTE tolerance due to a common fault without an alert received at the user receiver antenna within 300 seconds, shall not exceed 6×10^{-5} .

Note 1.— For B1I signals, the NTE tolerance is defined to be 4.42 times the upper bound of the URA range corresponding to the URA index (URAI) value being broadcast in D1 navigation messages, as described in Appendix B, section 3.1.4.1.3.1.2.

Note 2.— For B1C and B2a signals, the NTE tolerance is defined to be 4.42 times the signal-in-space accuracy (SISA) value calculated as described in Appendix B, section 3.1.4.2.5.

Note 3.— The mapping between BDS B1I SIS status and BDS B1I flags contained in the navigation data message is specified in Appendix B, 3.1.4.1.3.1.3. The mapping between BDS B1C and B2a SIS status and BDS B1C and B2a flags contained in the navigation data message is specified in Appendix B, 3.1.4.1.3.2.7.2.

3.7.3.1.4.5 *Continuity.* The probability of losing BDS OS SIS availability from a slot of the nominal 27-slot constellation due to unscheduled interruption, shall not exceed the following limits:

<i>Signals</i>	B1I	B1C	B2a
MEO	2×10^{-3} per hour	2×10^{-3} per hour	2×10^{-3} per hour
IGSO	5×10^{-3} per hour	2×10^{-3} per hour	2×10^{-3} per hour

Note.— Continuity applies under the condition that the satellite is broadcasting a healthy indication.

3.7.3.1.4.6 *Coverage.* BDS OS shall cover the surface of the earth up to an altitude of 1 000 km.

3.7.3.1.4.7 Radio frequency (RF) characteristics

Note.— Detailed BDS OS signals RF characteristics are specified in Appendix B, 3.1.4.1.1.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 53

3.7.3.1.4.8 *BII radio frequency (RF) characteristics*

3.7.3.1.4.8.1 *BII carrier frequency.* Each BDS-3 MEO or IGSO satellite shall broadcast a BDS BII OS signal at the carrier frequency of 1 561.098 MHz using code division multiple access (CDMA).

3.7.3.1.4.8.2 *BII signal spectrum.* The BDS OS BII signal power shall be contained within a ± 2.046 MHz band (1 559.052 – 1 563.144 MHz) centred on the 1 561.098 MHz frequency.

3.7.3.1.4.8.3 *BII signal polarization.* The transmitted BII RF signal shall be right-hand circularly polarized.

3.7.3.1.4.8.4 *BII signal power levels*

3.7.3.1.4.8.4.1 Each BDS-3 MEO satellite shall broadcast a BII navigation signal with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna is within the range of -163 dBW to -154.8 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.1.4.8.4.2 Each BDS-3 IGSO satellite shall broadcast a BII navigation signal with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna is within the range of -163 dBW to -156.5 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.1.4.8.5 *BII signal modulation.* The BDS OS BII signal shall be binary phase shift key (BPSK) modulated.

3.7.3.1.4.9 *BIC radio frequency (RF) characteristics*

3.7.3.1.4.9.1 *BIC carrier frequency.* Each BDS-3 MEO or IGSO satellite shall broadcast a BDS OS BIC signal at the carrier frequency of 1 575.42 MHz using CDMA.

3.7.3.1.4.9.2 *BIC signal spectrum.* The BDS OS signal power on BIC shall be contained within a 32.736 MHz band centred on the BIC frequency.

3.7.3.1.4.9.3 *BIC signal polarization.* The transmitted BIC RF signal shall be right-hand circularly polarized.

3.7.3.1.4.9.4 *BIC signal power levels*

3.7.3.1.4.9.4.1 Each BDS-3 MEO satellite shall broadcast a BIC navigation signal with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly-

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 54

polarized antenna is within the range of -159 dBW to -152.5 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.1.4.9.4.2 Each BDS-3 IGSO satellite shall broadcast a B1C navigation signal with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna is within the range of -161 dBW to -153.5 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.1.4.9.5 *B1C signal modulation.* The B1C signal shall comprise two components, known as B1C data component and B1C pilot component. The B1C data component shall be sine-phased binary offset carrier (BOC) modulated with the Modulo-2 addition of the ranging code and the navigation data. The B1C pilot component shall be quadrature multiplexed BOC (QMBOC) modulated with the ranging code. Ranging codes on B1C data component and B1C pilot component shall have the same chipping rate of 1.023 megachips per second.

Note. — Additional information concerning B1C modulation is given in the *BeiDou Navigation Satellite System Signal in Space Interface Control Document Open Service Signal B1C (Version 1.0)*, dated December 2017 (hereinafter referred to as “BDS OS B1C ICD”), section 4.2.

3.7.3.1.4.10 *B2a radio frequency (RF) characteristics*

3.7.3.1.4.10.1 *B2a carrier frequency.* Each BDS-3 MEO and IGSO satellite shall broadcast a BDS OS B2a signal at the carrier frequency of 1 176.45 MHz using CDMA.

3.7.3.1.4.10.2 *B2a signal spectrum.* The BDS OS signal power on B2a shall be contained within a 20.46 MHz band centred on the B2a frequency.

3.7.3.1.4.10.3 *B2a signal polarization.* The transmitted B2a RF signal shall be right-hand circularly polarized.

3.7.3.1.4.10.4 *B2a signal power levels*

3.7.3.1.4.10.4.1 Each BDS-3 MEO satellite shall broadcast a B2a navigation signal with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna is within the range of -156 dBW to -148.5 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.1.4.10.4.2 Each BDS-3 IGSO satellite shall broadcast a B2a navigation signal with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly-polarized antenna is within the range of -158 dBW to -150.5 dBW for all antenna orientations orthogonal to the direction of propagation.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 55

3.7.3.1.4.10.5 *B2a signal modulation.* The B2a signal shall comprise two components, known as B2a data component and B2a pilot component. The B2a data component shall be BPSK modulated with the Modulo-2 addition of the ranging code and the navigation data. The B2a pilot component shall be BPSK modulated with the ranging code. Ranging codes on B2a data component and B2a pilot component shall have the same chipping rate of 10.23 megachips per second.

Note.— Additional information concerning B2a modulation is given in the BeiDou Navigation Satellite System Signal In Space Interface Control Document Open Service Signal B2a (Version 1.0), dated December 2017 (hereinafter referred to as “BDS OS B2a ICD”), section 4.2.

3.7.3.1.4.11 *BDS time.* BDS time (BDT) shall be referenced to UTC as maintained by the National Time Service Center (NTSC), Chinese Academy of Sciences.

Note. — BDT details are specified in Appendix B, section 3.1.4.4.

3.7.3.1.4.12 *Coordinate system.* The BDS coordinate system shall be BeiDou Coordinate System (BDCS).

Note. — BDCS details are specified in Appendix B, section 3.1.4.5.

3.7.3.1.4.13 *Navigation information.* The navigation data transmitted by the satellites shall include the necessary information to determine:

- a) satellite time of transmission;
- b) satellite position;
- c) satellite health;
- d) satellite clock correction;
- e) ionospheric delay effects;
- f) time transfer to UTC; and
- g) constellation status.

3.7.3.2 Reserved

3.7.3.3 Aircraft-based augmentation system (ABAS)

3.7.3.3.1 *Performance.* The ABAS function combined with one or more of the other GNSS elements and both a fault-free GNSS receiver and fault-free aircraft system used for the ABAS function shall meet the requirements for accuracy, integrity, continuity and availability as stated in 3.7.2.4 for the intended operation.

Note. — For GNSS receivers supporting the ABAS function, the requirements to be resistant to interference, as specified in 3.7.4, apply.

3.7.3.4 Satellite-based augmentation system (SBAS)

Note. — All SBAS have to fulfil the requirements introduced in this section and in Appendix B, 3.5 except when a specific condition is mentioned in the requirement such as the provision of optional functions.

3.7.3.4.1 *Performance.* SBAS combined with one or more of the other GNSS elements and a fault-free receiver shall meet the requirements for system accuracy, integrity, continuity and availability for the intended operation as stated in 3.7.2.4, throughout the corresponding service area (see 3.7.3.4.4).

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 56

Note. — SBAS complements the core satellite constellation(s) by increasing accuracy, integrity, continuity and availability of navigation provided within a service area, typically including multiple aerodromes.

3.7.3.4.1.1 SBAS combined with one or more of the other GNSS elements and a fault-free receiver shall meet the requirements for signal-in-space integrity as stated in 3.7.2.4, throughout the SBAS coverage area.

Note. — For L1 SBAS message types 27 or 28 can be used to comply with the integrity requirements in the coverage area. Additional guidance on the rationale and interpretation of this requirement is provided in Attachment D, 3.3 and 6.2.3.

3.7.3.4.2 Functions. SBAS shall perform one or more of the following functions:

- a) L1SBS ranging: provide an additional L1 ranging signal with an accuracy indicator from an SBAS satellite (3.7.3.4.3 and Appendix B, 3.5.7.2);
- b) L1 SBS GNSS satellite status: determine and transmit the GNSS satellite health status (Appendix B, 3.5.7.3);
- c) L1SMS basic differential correction: provide GNSS satellite ephemeris and clock corrections (fast and long-term) to be applied to the L1 pseudo-range measurements from satellites (Appendix B, 3.5.7.4);
- d) L1SBS precise differential correction: determine and transmit the L1 ionospheric corrections and associated integrity data (Appendix B, 3.5.7.5).
- e) dual-frequency, multi-constellation (DFMC) SBAS ranging: provide additional ionosphere-free ranging capability using L1 and L5 signals from SBAS satellites (Appendix B, 3.5.14.2); and
- f) DFMC SBAS ionosphere-free differential correction: determine and transmit GNSS satellite health status, satellite ephemeris and clock corrections to be applied to the ionosphere-free pseudo-range measurements from satellites (Appendix B, 3.5.14.3) and associated integrity data.

Note 1.— For single-frequency users, if functions b) and c) are provided, SBAS in combination with core satellite constellation(s) can support departure, en-route, terminal and non-precision approach operations, and if function d) is provided in addition to b) and c), then SBAS can also support precision approach operations including Category I. The level of performance that can be achieved depends upon the infrastructure incorporated into SBAS and the ionospheric conditions in the geographic area of interest.

Note 2.— For dual-frequency users, if function f) is provided, SBAS in combination with core satellite constellation(s) can support departure, en-route, terminal, non-precision approach operations and precision approach operations including Category I.

Note 3.— In order to provide function e), SBAS needs to broadcast an L1 signal that meets the requirements for ionosphere-free ranging using L1 and L5 pseudo-range measurements.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 57

Note 4.— The ionospheric corrections are only broadcast on L1. Dual-frequency users will use an ionosphere-free pseudo-range measurement and not require ionospheric corrections. Ionosphere-free pseudo-range combination for DFMC SBAS is further defined in Appendix B, 3.5.15.1.

3.7.3.4.3 Ranging When SBAS is providing a ranging service, the following Standards shall apply:

3.7.3.4.3.1 Excluding atmospheric effects, the range error for the ranging signal from SBAS satellites shall not exceed 25 m (82 ft) (95 per cent).

3.7.3.4.3.2 The probability that the L1SBAS range error exceeds 150 m (490 ft) in any hour shall not exceed 10^{-5} .

3.7.3.4.3.3 The probability of unscheduled outages of the ranging function from an SBAS satellite in any hour shall not exceed 10^{-3} .

3.7.3.4.3.4 The range rate error shall not exceed 2 m (6.6 ft) per second.

3.7.3.4.3.5 The range acceleration error shall not exceed 0.019 m (0.06 ft) per second-squared.

3.7.3.4.4 Service area. An SBAS service area for any approved type of operation shall be a declared area within the SBAS coverage area where SBAS meets the corresponding requirements of 3.7.2.4.

Note 1. — An SBAS system can have different service areas corresponding to different types of operation (e.g. APV-I, Category I, etc.).

Note 2 - The coverage area is that area within which the SBAS broadcast can be received (i.e. the union of SBAS satellite footprints).

Note 3 - SBAS coverage and service areas are discussed in Attachment D, 6.2.

3.7.3.4.5 RF characteristics for the SBAS L1 signal

Note - Detailed RF characteristics are specified in Appendix B, 3.5.2 for L1.

3.7.3.4.5.1 L1Carrier frequency. The L1 carrier frequency shall be 1 575.42 MHz.

3.7.3.4.5.2 L1 Signal spectrum. At least 95 per cent of theL1 broadcast power shall be contained within a ± 12 MHz band centered on the L1 frequency. The bandwidth of the L1 signal transmitted by an SBAS satellite shall be at least 2.2 MHz.

Note. — The SBAS L1 RF link needs to provide a higher transmission bandwidth to support the SBAS ranging accuracy figure in Appendix B, 3.5.15.4.1, for DFMC SBAS ranging service. A higher transmission bandwidth will improve the performance of the L1 SBAS ranging service. See Attachment D, 6.4.6.

3.7.3.4.5.3 L1 satellite signal power level

3.7.3.4.5.3.1 Each SBAS satellite placed in orbit before 1 January 2014 shall broadcast navigation signals on L1 with sufficient power such that, at all unobstructed locations near the ground from which the satellite

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 58

is observed at an elevation angle of 5 degrees or higher, the level of the received RF signal at the antenna port of a 3 dBi linearly polarized antenna is within the range of –161 dBW to –153 dBW for all antenna orientations orthogonal to the direction of propagation.

3.7.3.4.5.3.2 Each SBAS satellite broadcasting an SBAS L1 signal placed in orbit after 31 December 2013 shall comply with the following requirements:

- a) The satellite shall broadcast navigation signals on L1 with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at or above the minimum elevation angle for which a trackable Geostationary orbit (GEO) satellite signal needs to be provided, the level of the received RF signal at the antenna port of the antenna specified in Appendix B, Table B-88A, is at least –164.0 dBW.
- b) The minimum elevation angle used to determine GEO coverage shall not be less than 5 degrees for a user near the ground.
- c) The level of a received SBAS RF signal on L1 at the antenna port of a 0 dBic antenna located near the ground shall not exceed –152.5 dBW.
- d) The ellipticity of the broadcast L1 signal shall be no worse than 2 dB for the angular range of $\pm 9.1^\circ$ from boresight.

3.7.3.4.5.4 Polarization. The broadcast signal shall be right-hand circularly polarized.

3.7.3.4.5.5 Modulation. The transmitted sequence on L1 shall be the Modulo-2 addition of the navigation message at a rate of 500 symbols per second and the 1023-bit pseudo-random noise code. It shall then be BPSK-modulated onto the carrier at a rate of 1.023 megachips per second.

3.7.3.4.6 *RF characteristics for the SBAS L5 signal*

Note. — Detailed RF characteristics are specified in Appendix B, 3.5.9 for L5.

3.7.3.4.6.1 *L5 carrier frequency.* The L5 carrier frequency shall be 1 176.45 MHz.

3.7.3.4.6.2 *L5 signal spectrum.* At least 95 per cent of the L5 broadcast power shall be contained within a bandwidth centred on the L5 frequency and between 20 MHz and 24 MHz.

3.7.3.4.6.3 *L5 signal power level.* Each SBAS satellite broadcasting an SBAS L5 signal shall comply with the following additional requirements:

- a) The satellite shall broadcast navigation signals on L5 with sufficient power such that, at all unobstructed locations near the ground from which the satellite is observed at or above the minimum elevation angle for which a trackable signal needs to be provided, the level of the received RF signal at the output of a 3 dBi linearly polarized antenna shall be at least –158 dBW for all antenna orientations orthogonal to the direction of propagation.
- b) The minimum elevation angle used to determine SBAS satellite coverage shall not be less than 5 degrees for a user near the ground.
- c) The level of a received SBAS RF signal on L5 at the output of a 0 dBic right-hand circularly polarized antenna located near the ground shall not exceed –150.5 dBW.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 59

- d) The ellipticity of the broadcast L5 signal shall be no worse than 2 dB for the angular range of $\pm 9.1^\circ$ from boresight.

Note. — The received signal levels, from a) and c), are measured within a ± 10 MHz frequency band centred on the L5 frequency.

3.7.3.4.6.4 *Polarization.* The broadcast signal on L5 shall be right-hand circularly polarized.

3.7.3.4.6.5 *Modulation.* The transmitted sequence on L5 in-phase shall be the result of the 250-bits of the navigation message with forward error correction (FEC) applied for 500 symbols per second that is then binary encoded and finally combined with the 10 230-bit pseudo-random noise code using Modulo-2 addition. The resulting sequence shall then be BPSK-modulated onto the carrier at a rate of 10.23 megachips per second.

Note.— Detailed L5 modulation characteristics for L5 are specified in Appendix B, 3.5.9.

3.7.3.4.7 *Timing*

3.7.3.4.7.1 *SBAS network time (SNT) for L1 SBAS.* The difference between SNT of the SBAS corrections on L1 and GPS time shall not exceed 50 nanoseconds.

3.7.3.4.7.2 *SBAS network time (SNT) for DFMC SBAS.* The difference between SNT of the SBAS corrections broadcast on L5 and the reference time of the core constellation designated as reference constellation (see the time reference identifier parameter in Appendix B, 3.5.11.4 broadcast by DFMC SBAS) shall not exceed 1 microsecond.

3.7.3.4.8 *L1 SBAS Navigation information.* The navigation data transmitted by SBAS satellites shall include the necessary information to support L1 SBAS services to determine:

- a) SBAS satellite time of transmission;
- b) SBAS satellite position;
- c) corrected satellite time for all satellites;
- d) corrected satellite position for all satellites;
- e) ionospheric propagation delay effects;
- f) user position integrity;
- g) time transfer to UTC (optional); and
- h) service level status.

Note - Structure and contents of data are specified in Appendix B, 3.5.3 and 3.5.4, respectively.

3.7.3.4.9 *DFMC SBAS navigation information.* The navigation data transmitted by an SBAS satellite on L5 shall include the necessary information to support DFMC SBAS services to determine:

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 60

- a) SBAS satellite time of transmission;
- b) SBAS satellite position;
- c) corrected satellite time for all monitored satellites;
- d) corrected satellite position for all monitored satellites;
- e) user position integrity; and
- f) time transfer to UTC (optional).

Note.— Structure and contents of data are specified in Appendix B, 3.5.10 and 3.5.11, respectively.

3.7.3.5 Ground-based augmentation system (GBAS) and ground-based regional augmentation system (GRAS)

Note-1 - Except where specifically annotated, GBAS Standards and Recommended Practices apply to GBAS and GRAS.

3.7.3.5.1 Performance. GBAS combined with one or more of the other GNSS elements and a fault-free GNSS receiver shall meet the requirements for system accuracy, continuity, availability and integrity for the intended operation as stated in 3.7.2.4 within the service volume for the service used to support the operation as defined in 3.7.3.5.3.

Note - GBAS is intended to support all types of approach, landing, guided take-off, departure and surface operations and may support en-route and terminal operations. GRAS is intended to support en-route, terminal, non-precision approach, departure, and approach with vertical guidance. The following SARPs are developed to support all categories of precision approach, approach with vertical guidance, and a GBAS positioning service

3.7.3.5.2 Functions. GBAS shall perform the following functions:

- a) provide locally relevant pseudo-range corrections;
- b) provide GBAS-related data;
- c) provide final approach segment data when supporting precision approach;
- d) provide predicted ranging source availability data; and
- e) provide integrity monitoring for GNSS ranging sources.

3.7.3.5.3 Service volume

3.7.3.5.3.1 General requirement for approach services. The minimum GBAS approach service volume shall be as follows, except where topographical features dictate and operational requirements permit:

- a) laterally, beginning at 140 m (450 ft) each side of the landing threshold point/fictitious threshold point (LTP/FTP) and projecting out ± 35 degrees either side of the final approach path to 28 km (15 NM) and ± 10 degrees either side of the final approach path to 37 km (20 NM); and

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 61

- b) vertically, within the lateral region, up to the greater of 7 degrees or 1.75 promulgated glide path angle (GPA) above the horizontal with an origin at the glide path interception point (GPIP) to an upper bound of 3 000 m (10 000 ft) height above threshold (HAT) and 0.45 GPA above the horizontal or to such lower angle, down to 0.30 GPA, as required, to safeguard the promulgated glide path intercept procedure. The lower bound is half the lowest decision height supported or 3-7 m (12 ft), whichever is larger.

Note 1 - LTP/FTP and GPIP are defined in Appendix B, 3.6.4.5.1.

Note 2 - Guidance material concerning the approach service volume is provided in Attachment D, 7.3.

3.7.3.5.3.2 *Approach services supporting autoland and guided take-off.* The minimum additional GBAS service volume to support approach operations that include automatic landing and rollout, including during guided take-off, shall be as follows, except where operational requirements permit:

- a) Horizontally within a sector spanning the width of the runway beginning at the stop end of the runway and extending parallel with the runway centre line towards the LTP to join the minimum service volume as described in 3.7.3.5.3.1.
- b) Vertically, between two horizontal surfaces one at 3.7 m (12 ft) and the other at 30 m (100 ft) above the runway centreline to join the minimum service volume as described in 3.7.3.5.3.1.

Note.— Guidance material concerning the approach service volume is provided in Attachment D, 7.3.

3.7.3.5.3.3 GBAS positioning service. The service volume for the GBAS positioning service shall be where the data broadcast can be received and the positioning service meets the requirements of 3.7.2.4 and supports the corresponding approved operations.

Note - Guidance material concerning the positioning service volume is provided in Attachment D, 7.3.

3.7.3.5.4 Data broadcast characteristics

Note - RF characteristics are specified in Appendix B, 3.6.2.

3.7.3.5.4.1 Carrier frequency. The data broadcast radio frequencies used shall be selected from the radio frequencies in the band 108 to 117.975 MHz. The lowest assignable frequency shall be 108.025 MHz and the highest assignable frequency shall be 117.950 MHz. The separation between assignable frequencies (channel spacing) shall be 25 kHz.

Note 1 - Guidance material on VOR/GBAS frequency assignments and geographical separation criteria is given in Attachment D, 7.2.1.

Note 2 - ILS/GBAS geographical separation criteria and geographical separation criteria for GBAS and VHF communication services operating in the 118 – 137 MHz band are under development. Until these criteria are defined and included in SARPs, it is intended that frequencies in the band 112.050 – 117.900 MHz will be used.

3.7.3.5.4.2 Access technique. A time division multiple access (TDMA) technique shall be used with a fixed frame structure. The data broadcast shall be assigned one to eight slots.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 62

Note - Two slots is the nominal assignment. Some GBAS facilities that use multiple VHF data broadcast (VDB) transmit antennas to improve VDB coverage may require assignment of more than two time slots. Guidance on the use of multiple antennas is given in Attachment D, 7.12.4; some GBAS broadcast stations in a GRAS may use one time slot.

3.7.3.5.4.3 Modulation. GBAS data shall be transmitted as 3-bit symbols, modulating the data broadcast carrier by D8PSK, at a rate of 10 500 symbols per second.

3.7.3.5.4.4 Data broadcast RF field strength and polarization

Note 1- GBAS can provide a VHF data broadcast with either horizontal (GBAS/H) or elliptical (GBAS/E) polarization that employs both horizontal polarization (HPOL) and vertical polarization (VPOL) components. Aircraft using a VPOL component will not be able to conduct operations with GBAS/H equipment. Relevant guidance material is provided in Attachment D, 7.1.

Note 2.— The minimum and maximum field strengths are consistent with a minimum distance of 80 m (263 ft) from the transmitter antenna for a range of 43 km (23 NM).

Note 3.— When supporting approach services at airports with challenging VDB transmitter siting constraints, it is acceptable to adjust the service volume when operational requirements permit (as stated in the service volume definition sections 3.7.3.5.3.1 and 3.7.3.5.3.2). Such adjustments of the service volume may be operationally acceptable when they have no impact on the GBAS service outside a radius of 80 m from the VDB antenna, assuming a nominal effective isotropic radiated power of 47dBm (Attachment D, Table D-3).

3.7.3.5.4.4.1 GBAS/H

3.7.3.5.4.4.1.1 A horizontally polarized signal shall be broadcast.

3.7.3.5.4.4.1.2 The effective isotropically radiated power (EIRP) shall provide for a horizontally polarized signal with a minimum field strength of 215 microvolts per meter (-99 dBW/m²) and a maximum field strength of 0.879 volts per meter (27 dBW/m²) within the GBAS service volume as specified in 3.7.3.5.3.1. The field strength shall be measured as an average over the period of the synchronization and ambiguity resolution field of the burst. Within the additional GBAS service volume as specified in 3.7.3.5.3.2, the effective isotropic radiated power (EIRP) shall provide for a horizontally polarized signal with a minimum field strength of 215 microvolts per metre (-99 dBW/m₂) below 36 ft and down to 12 ft above the runway surface and 650 microvolts per metre (-89.5 dBW/m₂) at 36 ft or more above the runway surface.

Note.— Guidance material concerning the approach service volume is provided in Attachment D, 7.3.

3.7.3.5.4.4.2 GBAS/E

3.7.3.5.4.4.2.1 An elliptically polarized signal should be broadcast whenever practical.

3.7.3.5.4.4.2.2 When an elliptically polarized signal is broadcast, the horizontally polarized component shall meet the requirements in 3.7.3.5.4.4.1.2, and the effective isotropically radiated power (EIRP) shall provide

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 63

for a vertically polarized signal with a minimum field strength of 136 microvolts per meter (-103 dBW/m^2) and a maximum field strength of 0.555 volts per meter (-31 dBW/m^2) within the GBAS service volume. The field strength shall be measured as an average over the period of the synchronization and ambiguity resolution field of the burst.

3.7.3.5.4.5 Power transmitted in adjacent channels. The amount of power during transmission under all operating conditions when measured over a 25 kHz bandwidth centered on the i^{th} adjacent channel shall not exceed the values shown in Table 3.7.3.5-1 (located at the end of section 3.7).

3.7.3.5.4.6 Unwanted emissions. Unwanted emissions, including spurious and out-of-band emissions, shall be compliant with the levels shown in Table 3.7.3.5-2 (located at the end of section 3.7). The total power in any VDB harmonic or discrete signal shall not be greater than -53 dBm .

3.7.3.5.5 Navigation information. The navigation data transmitted by GBAS shall include the following information:

- a) pseudo-range corrections, reference time and integrity data;
- b) GBAS-related data;
- c) final approach segment data when supporting precision approach; and
- d) predicted ranging source availability data.

Note - Structure and contents of data are specified in Appendix B, 3.6.3.

3.7.3.6 Aircraft GNSS receiver

3.7.3.6.1 The aircraft GNSS receiver shall process the signals of those GNSS elements that it intends to use as specified in Appendix B, 3.1.1 (for GPS), Appendix B, 3.1.2 (for GLONASS), Appendix B, 3.1.3 (for Galileo), Appendix B, 3.1.4 (for BDS), Appendix B 3.3 (for combined core satellite constellations), Appendix B, 3.4 (for ABAS), Appendix B, 3.5 (for SBAS) and Appendix B, 3.6 (for GBAS and GRAS).

3.7.4 Resistance to interference

3.7.4.1 GNSS shall comply with performance requirements defined in 3.7.2.4 and Appendix B, 3.7 in the presence of the interference environment defined in Appendix B, 3.7.

Note.— GNSS elements operating within the frequency bands 1 164 – 1 215 MHz and 1 559 – 1 610 MHz are classified by the ITU as operating in the radionavigation-satellite service (RNSS). Those frequency bands also include global allocations to the aeronautical radionavigation service (ARNS). Both aeronautical uses of those services are considered “safety services” and are afforded special spectrum protection status in the ITU radio regulations. In order to achieve the performance objectives for precision approach guidance to be supported by the GNSS and its augmentations, RNSS/ARNS is intended to remain the only global allocation in the 1 164 – 1 215 MHz and 1 559 – 1 610 MHz band and emissions from systems in this and adjacent frequency bands are intended to be tightly controlled by national and/or international regulation.

3.7.5 Database

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 64

Note - SARPs applicable to aeronautical data are provided in BCAR 4, BCAR 11, ICAO Annex 14 and BCAR 15.

3.7.5.1 Aircraft GNSS equipment that uses a database shall provide a means to:

- a) update the electronic navigation database; and
- b) determine the Aeronautical Information Regulation and Control (AIRAC) effective dates of the aeronautical database.

Note - Guidance material on the need for a current navigation database in aircraft GNSS equipment is provided in Attachment D, 11.

————— INTENTIONALLY LEFT BLANK —————

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

Table 3.7.2.4-1 Signal-in-space performance requirements

Typical operation	Accuracy horizontal 95% (Notes 1 and 3)	Accuracy vertical 95% (Notes 1 and 3)	Integrity (Note 2)	Time-to-alert (Note 3)	Continuity (Note 4)	Availability (Note 5)
En-route	3.7 km (2.0 NM)	N/A	$1 - 1 \times 10^{-7}/h$	5 min	$1 - 1 \times 10^{-4}/h$ to $1 - 1 \times 10^{-8}/h$	0.99 to 0.99999
En-route, Terminal	0.74 km (0.4 NM)	N/A	$1 - 1 \times 10^{-7}/h$	15 s	$1 - 1 \times 10^{-4}/h$ to $1 - 1 \times 10^{-8}/h$	0.99 to 0.99999
Initial approach, Intermediate approach, Non-precision approach (NPA), Departure	220 m (720 ft)	N/A	$1 - 1 \times 10^{-7}/h$	10 s	$1 - 1 \times 10^{-4}/h$ to $1 - 1 \times 10^{-8}/h$	0.99 to 0.99999
Approach operations with vertical guidance (APV-I)	16.0 m (52 ft)	20 m (66 ft)	$1 - 2 \times 10^{-7}$ in any approach	10 s	$1 - 8 \times 10^{-6}$ per 15 s	0.99 to 0.99999
Approach operations with vertical guidance (APV-II)	16.0 m (52 ft)	8.0 m (26 ft)	$1 - 2 \times 10^{-7}$ in any approach	6 s	$1 - 8 \times 10^{-6}$ per 15 s	0.99 to 0.99999
Category I precision approach (Note 7)	16.0 m (52 ft)	6.0 m to 4.0 m (20 ft to 13 ft) (Note 6)	$1 - 2 \times 10^{-7}$ in any approach	6 s	$1 - 8 \times 10^{-6}$ per 15 s	0.99 to 0.99999

NOTES.—

- The 95th percentile values for GNSS position errors are those required for the intended operation at the lowest height above threshold (HAT), if applicable. Detailed requirements are specified in Appendix B and guidance material is given in Attachment D, 3.2.
- The definition of the integrity requirement includes an alert limit against which the requirement can be assessed. For Category I precision approach, a vertical alert limit (VAL) greater than 10 m for a specific system design may only be used if a system-specific safety analysis has been completed. Further guidance on the alert limits is provided in Attachment D, 3.3.6 to 3.3.10. These alert limits are:

Typical operation	Horizontal alert limit	Vertical alert limit
En-route (oceanic/continental low density)	7.4 km (4 NM)	N/A
En-route (continental)	3.7 km (2 NM)	N/A
En-route, Terminal	1.85 km (1 NM)	N/A
NPA	556 m (0.3 NM)	N/A
APV-I	40 m (130 ft)	50 m (164 ft)
APV- II	40 m (130 ft)	20.0 m (66 ft)
Category I precision approach	40 m (130 ft)	35.0 m to 10.0 m (115 ft to 33 ft)

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 66

3. The accuracy and time-to-alert requirements include the nominal performance of a fault-free receiver.
4. Ranges of values are given for the continuity requirement for en-route, terminal, initial approach, NPA and departure operations, as this requirement is dependent upon several factors including the intended operation, traffic density, complexity of airspace and availability of alternative navigation aids. The lower value given is the minimum requirement for areas with low traffic density and airspace complexity. The higher value given is appropriate for areas with high traffic density and airspace complexity (see Attachment D, 3.4.2). Continuity requirements for APV and Category I operations apply to the average risk (over time) of loss of service, normalized to a 15-second exposure time (see Attachment D, 3.4.3).
5. A range of values is given for the availability requirements as these requirements are dependent upon the operational need which is based upon several factors including the frequency of operations, weather environments, the size and duration of the outages, availability of alternate navigation aids, radar coverage, traffic density and reversionary operational procedures. The lower values given are the minimum availabilities for which a system is considered to be practical but are not adequate to replace non-GNSS navigation aids. For en-route navigation, the higher values given are adequate for GNSS to be the only navigation aid provided in an area. For approach and departure, the higher values given are based upon the availability requirements at airports with a large amount of traffic assuming that operations to or from multiple runways are affected but reversionary operational procedures ensure the safety of the operation (see Attachment D, 3.5).
6. A range of values is specified for Category I precision approach. The 4.0 m (13 feet) requirement is based upon ILS specifications and represents a conservative derivation from these specifications (see Attachment D, 3.2.7).
7. GNSS performance requirements intended to support Category II and III precision approach operations necessitate lower level requirements in the technical appendix (Appendix B, 3.6) to be applied in addition to these signal-in-space requirements (see Attachment D, 7.5.1).
8. The terms APV-I and APV-II refer to two levels of GNSS approach and landing operations with vertical guidance (APV) and these terms are not necessarily intended to be used operationally.

Table 3.7.3.5-1. GBAS broadcast power transmitted in adjacent channels

Channel	Relative power	Maximum power
1st adjacent	-40 dBc	12 dBm
2nd adjacent	-65 dBc	-13 dBm
4th adjacent	-74 dBc	-22 dBm
8th adjacent	-88.5 dBc	-36.5 dBm
16th adjacent	-101.5 dBc	-49.5 dBm
32nd adjacent	-105 dBc	-53 dBm
64th adjacent	-113 dBc	-61 dBm
76th adjacent and beyond	-115 dBc	-63 dBm

NOTES.—

1. The maximum power applies if the authorized transmitter power exceeds 150 W.
2. The relationship is linear between single adjacent points designated by the adjacent channels identified above.

Table 3.7.3.5-2. GBAS broadcast unwanted emissions

Frequency	Relative unwanted emission level (Note 2)	Maximum unwanted emission level (Note 1)
9 kHz to 150 kHz	-93 dBc (Note 3)	-55 dBm/1 kHz (Note 3)
150 kHz to 30 MHz	-103 dBc (Note 3)	-55 dBm/10 kHz (Note 3)
30 MHz to 106.125 MHz	-115 dBc	-57 dBm/100 kHz
106.425 MHz	-113 dBc	-55 dBm/100 kHz
107.225 MHz	-105 dBc	-47 dBm/100 kHz
107.625 MHz	-101.5 dBc	-53.5 dBm/10 kHz
107.825 MHz	-88.5 dBc	-40.5 dBm/10 kHz
107.925 MHz	-74 dBc	-36 dBm/1 kHz
107.9625 MHz	-71 dBc	-33 dBm/1 kHz
107.975 MHz	-65 dBc	-27 dBm/1 kHz
118.000 MHz	-65 dBc	-27 dBm/1 kHz
118.0125 MHz	-71 dBc	-33 dBm/1 kHz
118.050 MHz	-74 dBc	-36 dBm/1 kHz
118.150 MHz	-88.5 dBc	-40.5 dBm/10 kHz
118.350 MHz	-101.5 dBc	-53.5 dBm/10 kHz
118.750 MHz	-105 dBc	-47 dBm/100 kHz
119.550 MHz	-113 dBc	-55 dBm/100 kHz
119.850 MHz to 1 GHz	-115 dBc	-57 dBm/100 kHz
1 GHz to 1.7 GHz	-115 dBc	-47 dBm/1 MHz

NOTES.—

1. The maximum unwanted emission level (absolute power) applies if the authorized transmitter power exceeds 150 W.
2. The relative unwanted emission level is to be computed using the same bandwidth for desired and unwanted signals. This may require conversion of the measurement for unwanted signals done using the bandwidth indicated in the maximum unwanted emission level column of this table.
3. This value is driven by measurement limitations. Actual performance is expected to be better.
4. The relationship is linear between single adjacent points designated by the adjacent channels identified above.

3.8 Reserved

3.9 System characteristics of airborne ADF receiving systems

	Aeronautical telecommunication Volume - I	BCAR-10	
	Specification for radio navigation aids	Chapter: 3	Page: 68

3.9.1 Accuracy of bearing indication

3.9.1.1 The bearing given by the ADF system shall not be in error by more than plus or minus 5 degrees with a radio signal from any direction having a field strength of 70 microvolts per meter or more radiated from an LF/MF NDB or locator operating within the tolerances permitted by this BCAR and in the presence also of an unwanted signal from a direction 90 degrees from the wanted signal and:

- a) on the same frequency and 15 dB weaker; or
- b) plus or minus 2 kHz away and 4 dB weaker; or
- c) plus or minus 6 kHz or more away and 55 dB stronger.

Note.— The above bearing error is exclusive of aircraft magnetic compass error.

3.10 (Reserved)

3.11 (Reserved) Microwave landing system (MLS) characteristics

	Aeronautical telecommunication Volume – I	BCAR-10	
	Microwave Landing system (MLS) Characteristics	Appendix-A	Page: 1

**APPENDIX A. (RESERVED) MICROWAVE LANDING SYSTEM (MLS)
CHARACTERISTICS**

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 2

APPENDIX B. TECHNICAL SPECIFICATIONS FOR THE GLOBAL NAVIGATION SATELLITE SYSTEM (GNSS)

1. Definitions

GBAS/E. A ground-based augmentation system transmitting an elliptically-polarized VHF data broadcast.

GBAS/H. A ground-based augmentation system transmitting a horizontally-polarized VHF data broadcast.

Receiver. A subsystem that receives GNSS signals and includes one or more sensors.

Reserved (bits/words/fields). Bits/words/fields that are not allocated, but which are reserved for a particular GNSS application.

Spare (bits/words/fields). Bits/words/fields that are not allocated or reserved, and which are available for future allocation.

Note - All spare bits are set to zero.

2. General

Note - The following technical specifications supplement the provisions of Chapter 3, 3.7.

3. GNSS Elements

3.1 Core constellations

3.1.1 Global Positioning System (GPS) Standard Positioning Service (SPS) (L1 and L5)

3.1.1.1 Non-aircraft Elements

3.1.1.1.1 L1 Coarse acquisition (c/a) signal radio frequency (RF) Characteristics

3.1.1.1.1.1 Carrier phase noise. The carrier phase noise spectral density of the unmodulated L1 carrier shall be such that a phase locked loop of 10 Hz one-sided noise bandwidth is able to track the carrier to an accuracy of 0.1 radian (1 sigma).

3.1.1.1.1.2 Spurious emissions. In-band spurious emissions shall be at least 40 dB below the unmodulated L1 carrier over the allocated channel bandwidth.

3.1.1.1.1.3 Correlation loss. The loss in the recovered signal power due to imperfections in the L1 C/A signal modulation and waveform distortion shall not exceed \pm 0.6 dB for all GPS-II satellite generations and 0.3 dB for all GPS-III satellite generations.

Note -The loss in signal power is the difference between the broadcast power in an bandwidth and the signal power recovered by a noise-free, loss-free receiver with 1-chip correlator spacing and the same bandwidth.

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 3

3.1.1.1.1.4 L1 C/A code generation and timing. Each C/A code pattern $G_i(t)$ shall be formed by the Modulo-2 sum of two 1 023-bit linear patterns, G_1 and G_{2i} . The G_{2i} sequence shall be formed by effectively delaying the G_2 sequence by an integer number of chips. The G_1 and G_2 sequences shall be generated by 10-stage shift registers having the following polynomials as referred to in the shift register input:

- a) $G_1: X^{10} + X^3 + 1$; and
- b) $G_2: X^{10} + X^9 + X^8 + X^6 + X^3 + X^2 + 1$.

The initialization vector for the G_1 and G_2 sequences shall be “1111111111”. The G_1 and G_2 registers shall be clocked at a 1.023 MHz rate. Timing relationships related to the C/A code shall be as shown in Figure B-1.

Note. — Additional information on code phase assignments is given in IS-GPS-200K.

3.1.1.1.2 L1 data structure. The legacy navigation (LNAV) message shall be formatted as shown in Figure B-2. Each page, as shown in Figure B-6, shall utilize a basic format of a 1 500-bit-long frame with up to 5 sub-frames, each of 300 bits in length. All words shall be transmitted most significant bit (MSB) first.

Note.— The bit allocations depicted for subframes 4 and 5 in Figure B-6 apply only to satellites broadcasting PRN codes 1 – 32. See IS-GPS-200K for the bit allocations of subframes 4 and 5 for satellites broadcasting PRN codes 33 – 63.

3.1.1.1.2.1 Sub-frame structure. Each sub-frame and/or page of a sub-frame shall start with a telemetry (TLM) word followed by a handover word (HOW). The HOW shall be followed by 8 data words. Each word in each frame shall contain 6 parity bits. The TLM word and HOW formats shall be as shown in Figures B-3 and B-4, respectively.

3.1.1.1.2.2 End/start of week. At the end/start of week:

- a) the cyclic paging of sub-frames 1 through 5 shall restart with sub-frame 1 regardless of which sub-frame was last transmitted prior to the end/start of week; and
- b) the cycling of 25 pages of sub-frames 4 and 5 shall restart with page 1 of each of the sub-frames, regardless of which page was transmitted prior to the end/start of week. All upload and page cutovers shall occur on frame boundaries (i.e. Modulo 30 seconds relative to the end/start of week).

Note - New data in sub-frames 4 and 5 may start to be transmitted with any of the 25 pages of these sub-frames.

3.1.1.1.2.3 Data parity. Words 1 through 10 of sub-frames 1 through 5 shall each contain 6 parity bits as their least significant bits (LSBs). In addition, two non-information bearing bits shall be provided as bits 23 and 24 of words 2 and 10 for parity computation purposes.

3.1.1.1.2.4 Telemetry (TLM) word. Each TLM word shall be 30 bits long, occur every 6 seconds in the data frame and be the first word in each sub-frame. The TLM format shall be as shown in Figure B-3. Each TLM word shall begin with a preamble, followed by 16 reserved bits and 6 parity bits.

3.1.1.1.2.5 Handover word (HOW). The HOW shall be 30 bits long and shall be the second word in each subframe/page, immediately following the TLM word. A HOW shall occur every 6 seconds in the data frame. The

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

HOW format and content shall be as shown in Figure B-4. The full time-of-week (TOW) count shall consist of the 19 LSBs of the 29-bit Z-count (3.1.1.2.6). The HOW shall begin with the 17 MSBs of the TOW count. These 17 bits shall correspond to the TOW count at the 1.5-second epoch that occurs at the start (leading edge) of the next following subframe.

3.1.1.1.2.5.1 Bit 18. On satellites designed by configuration code 001, bit 18 shall be an “alert” flag. When this flag is raised (bit 18 is a “1”), it shall indicate to the user that the satellite user range accuracy (URA) may be worse than indicated in sub-frame 1 and that use of the satellite is at the user’s risk. 3.1.1.1.2.5.2 Bit 19. Bit 19 shall be reserved.

3.1.1.1.2.5.3 Bits 20, 21 and 22. Bits 20, 21 and 22 of the HOW shall provide the identification (ID) of the sub-frame in which that particular HOW is the second word. The ID code shall be as defined below:

ID	Code
1.	001
2.	010
3.	011
4.	100
5.	101

3.1.1.1.2.6 Satellite Z-count. Each satellite shall internally derive a 1.5-second epoch that shall contain a convenient unit for precisely counting and communicating time. Time stated in this manner shall be referred to as a Z-count. The Z-count shall be provided to the user as a 29-bit binary number consisting of two parts as follows.

3.1.1.1.2.6.1 Time-of-week (TOW) count. The binary number represented by the 19 LSBs of the Z-count shall be referred to as the TOW count and is defined as being equal to the number of 1.5-second epochs that have occurred since the transition from the previous week. The count shall be short- cycled such that the range of the TOW count is from 0 to 403 199 1.5-second epochs (equaling one week) and shall be reset to zero at the end of each week. The TOW count’s zero state shall be the 1.5-second epoch that is coincident with the start of the present week. A truncated version of the TOW count, consisting of its 17 MSBs, shall be contained in the HOW of the L1 downlink data stream. The relationship between the actual TOW count and its truncated HOW version shall be as indicated in Figure B-5.

Note -The above-mentioned epoch occurs at (approximately) midnight Saturday night/Sunday morning, where midnight is defined as 0000 hours on the UTC scale which is nominally referenced to the Greenwich Meridian.

3.1.1.1.2.6.2 Week count. The 10 MSBs of the Z-count shall be a binary representation of the sequential number assigned to the present GPS week (Modulo 1024). The range of this count shall be from 0 to 1 023. Its zero state shall be that week which starts with the 1.5- second epoch occurring at (approximately) the UTC zero time point (3.1.4). At the expiration of GPS week number 1 023, the GPS week number shall roll over to zero. The previous 1 024 weeks in conversions from GPS time to a calendar date shall be accounted for by the user.

3.1.1.1.3 L1 Data Content

3.1.1.1.3.1 Sub-frame 1 - satellite clock and health data. The content of words 3 through 10 of subframe 1 shall contain the clock parameters and other data as indicated in Table B-1. The parameters in a data set shall be valid during the interval of time in which they are transmitted and shall remain valid for an additional period of time after transmission of the next data set has started.

3.1.1.1.3.1.1 Week number. The 10 MSBs of word 3 shall contain the 10 MSBs of the 29-bit Z-count and shall represent the number of the current GPS week at the start of the data set transmission interval with all zeros indicating week “zero.” The GPS week number shall increment at each end/start of week epoch.

3.1.1.1.3.1.2 User range accuracy (URA). Bits 13 through 16 of word 3 shall provide a URA index, which prescribes the predicted satellite URA as shown in Table B-2. The integrity assured URA (IAURA) shall be the upper bound URA value corresponding to the URA index, as shown in the last column of Table B-2.

Note 1 - The URA does not include error estimates due to inaccuracies of the single-frequency ionospheric delay model.

Note 2 - The URA is a statistical indicator of the contribution of the apparent clock and ephemeris prediction accuracies to the ranging accuracies obtainable with a specific satellite based on historical data.

Note 3.— The nominal URA value for each URA index is also shown in Table B-2. The nominal URA is suitable for use as a prediction of the RMS signal-in-space pseudo-range errors for accuracy-related purposes.

Table B-1 Subframe 1 parameters

Parameter	Number of bits**	Scale factor (LSB)	Effective range***	Units
Week number	10	1		weeks
Satellite accuracy	4			
Satellite health	6	1		discretes
T_{GD}	8*	2^{-31}		seconds
IODC	10			
t_{oc}	16	2^4	604 784	seconds
a_{f2}	8*	2^{-55}		seconds/second ²
a_{f1}	16*	2^{-43}		seconds/second
a_{f0}	22*	2^{-31}		seconds

* Parameters so indicated are two’s complement, with the sign bit (+ or –) occupying the MSB.

** See Figure B-6 for complete bit allocation.

*** Unless otherwise indicated in this column, effective range is the maximum range.

Table B-2. User range accuracy

<i>URA index</i>	<i>URA (metres)</i>	<i>Nominal URA</i>	<i>Corresponding LAURA</i>
0	0.00 < URA ≤ 2.40	2 m	2.40 m
1	2.40 < URA ≤ 3.40	2.8 m	3.40 m
2	3.40 < URA ≤ 4.85	4 m	4.85 m
3	4.85 < URA ≤ 6.85	5.7 m	6.85 m
4	6.85 < URA ≤ 9.65	8 m	9.65 m
5	9.65 < URA ≤ 13.65	11.3 m	13.65 m
6	13.65 < URA ≤ 24.00	16 m	24.00 m
7	24.00 < URA ≤ 48.00	32 m	48.00 m
8	48.00 < URA ≤ 96.00	64 m	96.00 m
9	96.00 < URA ≤ 192.00	128 m	192.00 m
10	192.00 < URA ≤ 384.00	256 m	384.00 m
11	384.00 < URA ≤ 768.00	512 m	768.00 m
12	768.00 < URA ≤ 1 536.00	1 024 m	1 536.00 m
13	1 536.00 < URA ≤ 3 072.00	2 048 m	3 072.00 m
14	3 072.00 < URA ≤ 6 144.00	4 096 m	6 144.00 m
15	6 144.00 < URA (or no accuracy prediction is available – SPS users are advised to use the SV at their own risk)	No accuracy prediction is available – SPS users are advised to use the SV at their own risk	N/A

3.1.1.1.3.1.3 Health. The transmitting satellite 6-bit health indication shall be provided by bits 17 through 22 of word 3. The MSB shall indicate a summary of the health of the navigation data, where:

- a) 0 = all navigation data are valid; and
- b) 1 = some of the navigation data are not valid.

The 5 LSBs shall indicate the health of the signal components in accordance with Table B-3. The health indication shall be provided relative to the capabilities of each satellite as designated by the configuration code provided in page 25 of subframe 4. Any satellite that does not have a certain capability shall be indicated as “healthy” if the lack of this capability is inherent in its design or it has been configured into a mode which is normal from a receiver standpoint and does not require that capability. Additional health data shall be given in sub-frames 4 and 5.

Note - The data given in sub-frame 1 may differ from that shown in sub-frames 4 and/or 5 of other satellites since the latter may be updated at a different time.

Table B-3. Codes for health of satellite signal components

<i>MSB</i>					<i>LSB</i>	<i>Indication</i>
0	0	0	0	0	0	ALL SIGNALS OK
1	1	1	0	0	0	SATELLITE IS TEMPORARILY OUT — do not use this satellite during current pass
1	1	1	0	1	1	SATELLITE WILL BE TEMPORARILY OUT — use with caution
1	1	1	1	0	0	ONE OR MORE SIGNALS ARE DEFORMED*, HOWEVER THE RELEVANT URA PARAMETERS ARE VALID
1	1	1	1	1	1	MULTIPLE ANOMALIES PRESENT (other than those anomalies or conditions that would result in either of the two satellite temporary outages as codified above.)
All other combinations						SATELLITE EXPERIENCING CODE MODULATION AND/OR SIGNAL POWER LEVEL TRANSMISSION PROBLEMS. The user may not be able to acquire the satellite or may experience intermittent tracking problems if satellite is acquired.

*Deformed means one or more signals do not meet the requirements in IS-GPS-200K, Section 3.

3.1.1.1.3.1.4 Issue of data, clock (IODC). Bits 23 and 24 of word 3 in sub-frame 1 shall be the 2 MSBs of the 10-bit IODC term. Bits 1 through 8 of word 8 in sub-frame 1 shall contain the 8 LSBs of the IODC. The IODC shall indicate the issue number of data set. The transmitted IODC shall be different from any value transmitted by the satellite during the preceding 7 days.

Note - The relationship between the IODC and the Issue of Data, Ephemeris (IODE) terms is defined in 3.1.1.1.3.2.2.

3.1.1.1.3.1.5 Estimated group delay differential. Bits 17 through 24 of word 7 shall contain the correction term, T_{GD} , to account for the effect of satellite group delay differential.

Note - T_{GD} does not include any C/A to P(Y) code relative group delay error.

3.1.1.1.3.1.6 Satellite clock correction parameters. Bits 9 through 24 of word 8, bits 1 through 24 of word 9, and bits 1 through 22 of word 10 shall contain the parameters needed by the users for apparent satellite clock correction (t_{oc} , a_{f2} , a_{f1} and a_{f0}).

3.1.1.1.3.1.7 Reserved data fields. Reserved data fields shall be as indicated in Table B-4. All reserved data fields shall support valid parity within their respective words.

3.1.1.1.3.2 Sub frames 2 and 3 - satellite ephemeris data. Sub frames 2 and 3 shall contain the ephemeris representation of the transmitting satellite.

3.1.1.1.3.2.1 Ephemeris parameters. The ephemeris parameters shall be as indicated in Table B-5. For each parameter in sub frame 2 and 3, the number of bits, the scale factor of the LSB, the range, and the units shall be as specified in Table B-6.

3.1.1.1.3.2.2 Issue of data, ephemeris (IODE). The IODE shall be an 8-bit number equal to the 8 LSBs of the 10-bit IODC of the same data set. The IODE shall be provided in both sub frames 2 and 3 for the purpose of comparison with the 8 LSBs of the IODC term in sub frame 1. Whenever these three terms do not match, as a result of a data set cutover, new data shall be collected. The transmitted IODE shall be different from any value transmitted by the satellite during the preceding six hours (Note 1). Any change in the sub frame 2 and 3 data shall be accomplished in concert with a change in both IODE words. Change to new data sets shall occur only on hour boundaries except for the first data set of a new upload. Additionally, the t_{oe} value, for at least the first data set transmitted by a satellite after an upload, shall be different from that transmitted prior to the change (Note 2).

Table B-4. Subframe 1 reserved data fields

Word	Bit
3	11 – 12
4	1 – 24
5	1 – 24
6	1 – 24
7	1 – 16

Table B-5. Ephemeris data

M_0	Mean anomaly at reference time
Δn	Mean motion difference from computed value
e	Eccentricity
\sqrt{A}	Square root of the semi-major axis
OMEGA ₀	Longitude of ascending node of orbit plane at weekly epoch
i_0	Inclination angle at reference time
ω	Argument of perigee
OMEGADOT	Rate of right ascension
iDOT	Rate of inclination angle
C_{uc}	Amplitude of the cosine harmonic correction term to the argument of latitude
C_{us}	Amplitude of the sine harmonic correction term to the argument of latitude
C_{rc}	Amplitude of the cosine harmonic correction term to the orbit radius
C_{rs}	Amplitude of the sine harmonic correction term to the orbit radius
C_{ic}	Amplitude of the cosine harmonic correction term to the angle of inclination
C_{is}	Amplitude of the sine harmonic correction term to the angle of inclination
t_{oe}	Reference time, ephemeris
IODE	Issue of data, ephemeris

Table B-6. Ephemeris parameters

<i>Parameter</i>	<i>Number of bits**</i>	<i>Scale factor (LSB)</i>	<i>Effective range***</i>	<i>Units</i>
IODE	8			
C_{rs}	16*	2^{-5}		metres
Δn	16*	2^{-43}		semi-circles/second
M_0	32*	2^{-31}		semi-circles
C_{uc}	16*	2^{-29}		radians
e	32	2^{-33}	0.03	dimensionless
C_{us}	16*	2^{-29}		radians
\sqrt{A}	32	2^{-19}	2 530 to 8 192	metres ^{1/2}
t_{oe}	16	2^4	604 784	seconds
C_{ic}	16*	2^{-29}		radians
OMEGA ₀	32*	2^{-31}		semi-circles
C_{is}	16*	2^{-29}		radians
i_0	32*	2^{-31}		semi-circles
C_{rc}	16*	2^{-5}		metres
ω	32*	2^{-31}		semi-circles
OMEGADOT	24*	2^{-43}	-6.33×10^{-7} to 0	semi-circles/second
iDOT	14*	2^{-43}		semi-circles/second

* Parameters so indicated are two's complement, with the sign bit (+ or -) occupying the MSB.

** See Figure B-6 for complete bit allocation in subframe.

*** Unless otherwise indicated in this column, effective range is the maximum range attainable with the indicated bit allocation and scale factor.

Note 1. — The IODE/IODC terms provide the receiver with a means for detecting any changes in the ephemeris/clock representation parameters.

Note 2.— The first data set may change (3.1.1.1.2.2) at any time during the hour and therefore may be transmitted by the satellite for less than 1 hour.

3.1.1.1.3.2.3 *Curve fit intervals.* Bit 17 in word 10 of subframe 2 shall be a “fit interval” flag which indicates the curve-fit interval used in determining the ephemeris parameters, as follows:

0 = 4 hours,

1 = greater than 4 hours.

A fit interval flag of zero (0) shall indicate the satellite is undergoing normal operations. A fit interval flag of one (1) shall indicate the satellite is undergoing short- or long-term extended operations.

3.1.1.1.3.3 Sub frames 4 and 5 — support data. Both sub frames 4 and 5 shall be sub commutated 25 times each. With the possible exception of “reserved” pages and explicit repeats, each page shall contain different data in words 3 through 10. Subframes 4 and 5 shall contain the data listed in Table B-7.

Note. — Subframes 4 and 5 from satellites broadcasting PRN codes 1 – 32 contain almanac and health data for 32 satellites. Subframes 4 and 5 from satellites broadcasting PRN codes 33 – 63 contain almanac and health data for only 31 satellites. See IS-GPS-200K for full details on the content and bit allocations of the data in subframes 4 and 5.

Table B-7. Subframes 4 and 5 data

<i>Subframe</i>	<i>Page(s)</i>	<i>Data</i>
4	1, 6, 11, 16 and 21	Reserved
	2, 3, 4, 5, 7, 8, 9 and 10*	Almanac data
	12, 19, 20, 22, 23 and 24	Reserved
	13	NMCT**
	14 and 15	Reserved for system use
	17	Special messages**
	18	Ionospheric and UTC data
	25	A-S flags/SV configurations and SV health
5	1 through 24	Almanac data
	25	SV health data
<p>* Page 10 of subframe 4 is only sent from satellites broadcasting PRN codes 1 – 32 (and will contain almanac data for PRN 32); it is not used by satellites broadcasting PRN codes 33 – 63.</p> <p>** Page not intended for aviation use.</p>		

3.1.1.1.4 L5 SIGNAL RADIO FREQUENCY (RF) CHARACTERISTICS

3.1.1.1.4.1 *Carrier phase noise.* The carrier phase noise spectral density of the unmodulated L5 carrier shall be such that a phase locked loop of 10 Hz one-sided noise bandwidth can track the carrier to an accuracy of 0.1 radians RMS.

3.1.1.1.4.2 *Spurious emissions.* In-band spurious emissions shall be at least 40 dB below the unmodulated L5 carrier over the allocated channel bandwidth.

3.1.1.1.4.3 *Correlation loss.* The loss in the recovered signal power due to imperfections in the L5 signal modulation and waveform distortion shall not exceed 0.6 dB.

Note. — The loss in signal power is the difference between the broadcast power in an allocated bandwidth and the signal power recovered by a noise-free, loss-free receiver with 1-chip correlator spacing and the same bandwidth.

3.1.1.1.4.4 *L5 carrier components.* L5 shall have two carrier components modulated by separate bit trains: the I5-code and the Q5-code (see Table B-8).

3.1.1.1.4.4.1 The I5 and Q5 carriers shall be in phase quadrature (within ± 100 milliradians) and the Q5 carrier shall be lagging the I5 carrier by 90 degrees.

Table B-8. Composite L5 transmitted signal phase**

<i>Nominal composite L5 signal phase*</i>	<i>Code state</i>	
	I5	Q5
0°	0	0
-90°	1	0
+90°	0	1
180°	1	1
* Relative to 0, 0 code state with positive angles leading and negative angles lagging.		
** Based on the composite of two L5 carrier components at the same power.		

3.1.1.1.4.5 *Code generation.* The I5 and Q5 code patterns $I5_i(t)$ and $Q5_i(t)$ shall each be formed by the Modulo-2 sum of two extended bit patterns clocked at a 10.23 MHz rate, $XA(t)$ and $XBI_i(nI_i, t)$ or $XA(t)$ and $XBQ_i(nQ_i, t)$, where nI_i and nQ_i are the initial states of XBI_i and XBQ_i for satellite i .

3.1.1.1.4.5.1 The XA code shall be a code of length 8 190 with initial condition of all “ones” that is short-cycled 1 chip before its natural ending and restarted to run over a period of 1 millisecond (synchronized with the L1 frequency C/A code) for a total of 10 230 chips.

3.1.1.1.4.5.2 The XBI_i and XBQ_i codes shall be codes of length 8 191 with initial conditions that are specified in IS-GPS-705F, Tables 3-Ia and Ib. The XBI_i and XBQ_i codes shall not be short-cycled and shall be restarted to run over a period of 1 millisecond for a total of 10 230 chips.

3.1.1.1.4.5.3 The generating polynomials for the XA and XBI_i and XBQ_i codes shall be:

- a) XA: $X_{13} + X_{12} + X_{10} + X_9 + 1$; and
- b) XBI_i and XBQ_i : $X_{13} + X_{12} + X_8 + X_7 + X_6 + X_4 + X_3 + X + 1$.

Note. — Additional details on code phase assignments are specified in the GPS Interface Specification, IS-GPS-705F.

3.1.1.1.4.6 *Navigation data modulation.* The L5 navigation data (CNAV) bit train shall be encoded at a rate of 2 symbols per bit using a convolution code with a constraint length of 7 to yield 100 symbols per second (sps). The 100 sps symbols shall then be modulated (Modulo-2 addition) with the 10-bit Neuman-Hofman code “0000110101” clocked at 1 kHz. The resulting symbol sequence shall be Modulo-2 added with the I5 PRN code and used to modulate the L5 in-phase carrier.

3.1.1.1.4.7 *Signal timing.* The XA code shall be synchronized with the L1 frequency C/A code. The XBI_i and XBQ_i codes shall be synchronized with the XA code.

3.1.1.1.4.8 *Group delay differential.* The absolute value of the mean differential delay between the radiated L1 and L5 signals shall not exceed 30.0 nanoseconds. The total variation about the mean (random plus non-random variations) shall not exceed 3.0 nanoseconds (95 per cent probability).

Note. — *Inter-signal corrections (ISCs) are provided in the navigation data, to correct for the bias component of the differential delay.*

3.1.1.1.5 L5 Data Structure

3.1.1.1.5.1 Forward error correction. The L5 CNAV bit train shall be rate 1/2 convolution encoded with a forward error correction (FEC) code of constraint length 7.

3.1.1.1.5.2 Navigation data structure. The L5 CNAV data shall be provided in a set of six-second 300-bit long messages.

3.1.1.1.5.2.1 Each message shall contain a cyclic redundancy check (CRC) parity block of 24 bits protecting the entire 300-bit message.

3.1.1.1.5.2.2 Each message shall be composed of the following ordered fields: an 8-bit preamble (“10001011”), the 6-bit PRN number of the transmitting satellite, a 6-bit message type ID (range 0 to 63), the 17-bit message time-of-week (TOW) count, a 1-bit alert flag (bit 38), the data field (238 bits), and the 24-bit CRC parity block.

3.1.1.1.5.2.3 The TOW count multiplied by 6 shall provide the satellite time in seconds at the start of the next 6-second message.

3.1.1.1.5.2.4 Bit 38 shall be an “alert flag” where the value “1” indicates that the signal URA components may be worse than indicated in the associated message types and that use of the signal is at the user’s risk.

3.1.1.1.6 L5 (CNAV) Data content

3.1.1.1.6.1 CNAV message types. The CNAV data broadcasted on L5 shall contain the message types listed in Table B-9.

Note. — See IS-GPS-705F for details on the content and application of the data contained in each message type.

Table B-L5-2. CNAV message types

Message type	Content
0	Default message (empty)
10	Ephemeris, accuracy, health parameters
11	Ephemeris, accuracy, health parameters
30	SV Clock, accuracy, ionosphere, group delay
31	SV Clock, accuracy, almanac
32	SV Clock, accuracy, earth orientation parameters
33	SV Clock, accuracy, UTC parameters
34	SV Clock, accuracy, differential correction parameters
35	SV Clock, accuracy, GPS/GNSS time offset
36	SV Clock, accuracy, text messages
37	SV Clock, accuracy, midi almanac

3.1.1.1.6.2 Message Type 10 shall contain the elevation-dependent (ED) component of the user range accuracy (URA_{ED}) index corresponding to the maximum elevation-dependent error expected for the current ephemeris curve fit for the worst-case location within the satellite footprint.

Note.— At the best location within the satellite footprint (i.e. nominally directly below the satellite along its nadir vector), the corresponding URA_{ED} is zero (see Table B-10).

3.1.1.1.6.3 Message Types 30 to 37 shall contain the non-elevation-dependent (NED) URA component indices: $URANED0$ index, $URANED1$ index, and $URANED2$ index, respectively, for the transmitting satellite.

The $URANED0$ value shall be related to the $URANED0$ index according to Table B-11.

The $URANED1$ value shall be related to the $URANED1$ index as:

$$URANED1 = \frac{1}{2^N}$$

Where

$$N = 14 + URANED1 \text{ index}$$

The $URANED2$ value shall be related to the $URANED2$ index as:

$$URANED2 = \frac{1}{2^N}$$

where

$$N = 28 + URANED2 \text{ index}$$

Note.— URA_{ED} , $URANED0$, $URANED1$ and $URANED2$ are used to compute the integrity assured URA (IAURA).

Table B-10. Elevation-dependent user range accuracy URA_{ED}

URA_{ED} index	URA_{ED} (m)
15	$6\ 144.00 < URA_{ED}$ (accuracy prediction not available)
14	$3\ 072.00 < URA_{ED} \leq 6\ 144.00$
13	$1\ 536.00 < URA_{ED} \leq 3\ 072.00$
12	$768.00 < URA_{ED} \leq 1\ 536.00$
11	$384.00 < URA_{ED} \leq 768.00$
10	$192.00 < URA_{ED} \leq 384.00$
9	$96.00 < URA_{ED} \leq 192.00$
8	$48.00 < URA_{ED} \leq 96.00$
7	$24.00 < URA_{ED} \leq 48.00$
6	$13.65 < URA_{ED} \leq 24.00$

5	$9.65 < \text{URA}_{ED} \leq 13.65$
4	$6.85 < \text{URA}_{ED} \leq 9.65$
3	$4.85 < \text{URA}_{ED} \leq 6.85$
2	$3.40 < \text{URA}_{ED} \leq 4.85$
1	$2.40 < \text{URA}_{ED} \leq 3.40$
0	$1.70 < \text{URA}_{ED} \leq 2.40$
- 1	$1.20 < \text{URA}_{ED} \leq 1.70$
- 2	$0.85 < \text{URA}_{ED} \leq 1.20$

- 13	$0.02 < UR_{NED0} \leq 0.03$
- 14	$0.01 < UR_{NED0} \leq 0.02$
- 15	$UR_{NED0} \leq 0.01$
- 16	Accuracy prediction not available

3.1.1.2 Definitions of Protocols for Data Application

Note. — This section defines the inter-relationships of the data broadcast message parameters. It provides definitions of parameters that are not transmitted, but are used by either or both non-aircraft and aircraft elements, and that define terms applied to determine the navigation solution and its integrity.

Table B-12. Parity encoding algorithms

D_1	$= d_1 \oplus D^*_{30}$
D_2	$= d_2 \oplus D^*_{30}$
D_3	$= d_3 \oplus D^*_{30}$
•	•
•	•
•	•
•	•
D_{24}	$= d_{24} \oplus D^*_{30}$
D_{25}	$= D^*_{29} \oplus d_1 \oplus d_2 \oplus d_3 \oplus d_5 \oplus d_6 \oplus d_{10} \oplus d_{11} \oplus d_{12} \oplus d_{13} \oplus d_{14} \oplus d_{17} \oplus d_{18} \oplus d_{20} \oplus d_{23}$
D_{26}	$= D^*_{30} \oplus d_2 \oplus d_3 \oplus d_4 \oplus d_6 \oplus d_7 \oplus d_{11} \oplus d_{12} \oplus d_{13} \oplus d_{14} \oplus d_{15} \oplus d_{18} \oplus d_{19} \oplus d_{21} \oplus d_{24}$
D_{27}	$= D^*_{29} \oplus d_1 \oplus d_3 \oplus d_4 \oplus d_5 \oplus d_7 \oplus d_8 \oplus d_{12} \oplus d_{13} \oplus d_{14} \oplus d_{15} \oplus d_{16} \oplus d_{19} \oplus d_{20} \oplus d_{22}$
D_{28}	$= D^*_{30} \oplus d_2 \oplus d_4 \oplus d_5 \oplus d_6 \oplus d_8 \oplus d_9 \oplus d_{13} \oplus d_{14} \oplus d_{15} \oplus d_{16} \oplus d_{17} \oplus d_{20} \oplus d_{21} \oplus d_{23}$
D_{29}	$= D^*_{30} \oplus d_1 \oplus d_3 \oplus d_5 \oplus d_6 \oplus d_7 \oplus d_9 \oplus d_{10} \oplus d_{14} \oplus d_{15} \oplus d_{16} \oplus d_{17} \oplus d_{18} \oplus d_{21} \oplus d_{22} \oplus d_{24}$
D_{30}	$= D^*_{29} \oplus d_3 \oplus d_5 \oplus d_6 \oplus d_8 \oplus d_9 \oplus d_{10} \oplus d_{11} \oplus d_{13} \oplus d_{15} \oplus d_{19} \oplus d_{22} \oplus d_{23} \oplus d_{24}$

where:

$D_1, D_2, D_3, \dots, D_{29}, D_{30}$ are the bits transmitted by the satellite;
 D_{25}, \dots, D_{30} are the computed parity bits;
 d_1, d_2, \dots, d_{24} are the source data bits;
 \oplus is the Modulo-2 or “Exclusive-Or” operation; and
 $*$ is used to identify the last two bits of the previous word of the subframe.

3.1.1.2.1 GPS protocols for single-frequency L1 users

3.1.1.2.1.1 Parity algorithm. GPS parity algorithms are defined as indicated in Table B-12.

3.1.1.2.1.2 Satellite clock correction parameters. GPS system time t is defined as:

3.1.1.2.1.1 *Parity algorithm.* GPS parity algorithms are defined as indicated in Table B-12.

3.1.1.2.1.2 *Satellite clock correction parameters.* GPS system time t is defined as:

$$t = t_{sv} - (\Delta t_{sv})_{L1}$$

where

- t = GPS system time (corrected for beginning and end-of-week crossovers);
- t_{sv} = satellite time at transmission of the message;
- $(\Delta t_{sv})_{L1}$ = the satellite PRN code phase offset;
- $(\Delta t_{sv})_{L1} = a_0 + a_1(t - t_{oc}) + a_2(t - t_{oc})^2 + \Delta t_r - T_{GD}$

where

- a_0, a_1 and a_2 and t_{oc} , are contained in subframe 1; and
- Δt_r = the relativistic correction term (seconds)
- $\Delta t_r = F_e \sqrt{A} \sin E_k$

where

e and A are contained in subframes 2 and 3;
 E_k is defined in Table B-13; and

$$F = \frac{-2(\mu)^{1/2}}{c^2} = -4.442807633(10)^{-10} \text{ s/m}^{1/2}$$

where

μ = WGS-84 universal gravitational parameter ($3.986005 \times 10^{14} \text{ m}^3/\text{s}^2$)
 c = the speed of light in a vacuum ($2.99792458 \times 10^8 \text{ m/s}$)

Note. — The value of t is intended to account for the beginning or end-of-week crossovers. That is, if the quantity $t-t_{oc}$ is greater than 302 400 seconds, subtract 604 800 seconds from t . If the quantity $t-t_{oc}$ is less than -302 400 seconds, add 604 800 seconds to t .

3.1.1.2.1.3 Satellite position. The current satellite position (X_k, Y_k, Z_k) is defined as shown in Table B-13.

3.1.1.2.1.4 Ionospheric correction. The ionospheric correction (Tiono, L1) is defined as:

$$T_{\text{iono,L1}} = \begin{cases} F \times \left[5.0 \times 10^{-9} + \text{AMP} \left(1 - \frac{x^2}{2} + \frac{x^4}{24} \right) \right], & |x| < 1.57 \\ F \times (5.0 \times 10^{-9}) & , |x| \geq 1.57 \end{cases} \text{ (seconds)}$$

where

$$\text{AMP} = \begin{cases} \sum_{n=0}^3 \alpha_n \phi_m^n, & \text{AMP} \geq 0 \\ \text{if AMP} < 0, \text{AMP} = 0 \end{cases} \text{ (seconds)}$$

$$x = \frac{2\pi(t-50\,400)}{\text{PER}}, \text{ (radians)}$$

$$\text{PER} = \begin{cases} \sum_{n=0}^3 \beta_n \phi_m^n, & \text{PER} \geq 72\,000 \\ \text{if PER} < 72\,000, \text{PER} = 72\,000 \end{cases} \text{ (seconds)}$$

$$F = 1.0 + 16.0[0.53 - E]^3$$

α_n and β_n are the satellite transmitted data words with $n = 0, 1, 2$ and 3

$$\phi_m = \phi_1 + 0.064 \cos(\lambda_i - 1.617) \text{ (semi-circles)}$$

$$\lambda_i = \lambda_u + \frac{\psi \sin A}{\cos \phi_1} \text{ (semi-circles)}$$

$$\bar{\phi}_i = \phi_u + \psi \cos A \text{ (semi-circles)}$$

$$\phi_i = \begin{cases} \phi_i = \bar{\phi}_i & \text{if } |\bar{\phi}_i| \leq 0.416 \\ \phi_i = +0.416 & \text{if } \bar{\phi}_i > 0.416 \\ \phi_i = -0.416 & \text{if } \bar{\phi}_i < -0.416 \end{cases} \text{ (semi-circles)}$$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 18

$$\psi = \frac{0.0137}{E+0.11} - 0.022 \text{ (semi-circles)}$$

$$t = 4.32 \times 10^4 \lambda_i + \text{GPS time (seconds) where } 0 \leq t < 86\,400,$$

therefore: if $t \geq 86\,400$ seconds, subtract 86 400 seconds; and
if $t < 0$ seconds, add 86 400 seconds

$$E = \text{satellite elevation angle}$$

3.1.1.2.1.4.1 The terms used in computation of ionospheric delay are as follows:

a) Satellite transmitted terms

- α_n = the coefficients of a cubic equation representing the amplitude of the vertical delay (4 coefficients = 8 bits each) obtained from page 18 of subframe 4
- β_n = the coefficients of a cubic equation representing the period of the model (4 coefficients = 8 bits each) obtained from page 18 of subframe 4

b) Receiver generated terms

- E = elevation angle between the user and satellite (semi-circles)
- A = azimuth angle between the user and satellite, measured clockwise positive from the true North (semi-circles)
- ϕ_u = user geodetic latitude (semi-circles) WGS-84
- λ_u = user geodetic longitude (semi-circles) WGS-84
- GPS time = receiver computed system time

c) Computed terms

- x = phase (radians)
- F = obliquity factor (dimensionless)
- t = local time (seconds)
- ϕ_m = geomagnetic latitude of the earth projection of the ionospheric intersection point (mean ionospheric height assumed 350 km) (semi-circles)
- λ_i = geomagnetic longitude of the earth projection of the ionospheric intersection point (semi-circles)
- ϕ_i = geomagnetic latitude of the earth projection of the ionospheric intersection point (semi-circles)
- ψ = earth's central angle between user position and earth projection of ionospheric intersection point (semi-circles)

Table B-13. Elements of coordinate systems

$A = (\sqrt{A})^2$	Semi-major axis
$n_0 = \sqrt{\frac{\mu}{A^3}}$	Computed mean motion
$t_k = t - t_{oe}$	Time from ephemeris reference epoch*
$n = n_0 + \Delta n$	Corrected mean motion
$M_k = M_0 + nt_k$	Mean anomaly
$M_k = E_k - e \sin E_k$	Kepler's equation for eccentric anomaly (may be solved by iteration)
$v_k = \tan^{-1} \left\{ \frac{\sin v_k}{\cos v_k} \right\} = \tan^{-1} \left\{ \frac{\sqrt{1-e^2} \sin E_k / (1-e \cos E_k)}{(\cos E_k - e) / (1-e \cos E_k)} \right\}$	True anomaly
$E_k = \cos^{-1} \left\{ \frac{e + \cos v_k}{1 + e \cos v_k} \right\}$	Eccentric anomaly
$\phi_k = v_k + \omega$	Argument of latitude
Second Harmonic Perturbations	
$\delta u_k = C_{us} \sin 2\phi_k + C_{uc} \cos 2\phi_k$	Argument of latitude correction
$\delta r_k = C_{rc} \sin 2\phi_k + C_{rs} \cos 2\phi_k$	Radius correction
$\delta i_k = C_{ic} \cos 2\phi_k + C_{is} \sin 2\phi_k$	Inclination correction
$u_k = \phi_k + \delta u_k$	Corrected argument of latitude
$r_k = A(1 - e \cos E_k) + \delta r_k$	Corrected radius
$i_k = i_0 + \delta i_k + (iDOT)t_k$	Corrected inclination
$\begin{cases} x'_k = r_k \cos u_k \\ y'_k = r_k \sin u_k \end{cases}$	Positions in orbital plane
$\Omega_k = \Omega_0 + (\dot{\Omega} - \dot{\Omega}_e)t_k - \dot{\Omega}_e t_{oe}$	Corrected longitude of ascending node
$\begin{cases} x_k = x'_k \cos \Omega_k - y'_k \sin \Omega_k \\ y_k = x'_k \sin \Omega_k + y'_k \cos \Omega_k \\ z_k = y'_k \sin i_k \end{cases}$	Earth-centred, earth-fixed coordinates
* t is GPS system time at time of transmission, i.e. GPS time corrected for transit time (range/speed of light). Furthermore, t_k is the actual total time difference between the time t and the epoch time t_{oe} , and must account for beginning or end-of-week crossovers. That is, if t_k is greater than 302 400 seconds, subtract 604 800 seconds from t_k . If t_k is less than -302 400 seconds, add 604 800 seconds to t_k .	

3.1.1.2.2 GPS Protocols for single-frequency (15) and dual-frequency (11/15) users

3.1.1.2.2.1 *Parity algorithm.* The CNAV CRC word shall be calculated in the forward direction using a seed of 0. The sequence of 24 bits (p1, p2, ..., p24) shall be generated from the sequence of information bits (m1, m2, ..., m276) using the following generating polynomial:

$$g(X) = \sum_{i=0}^{24} g_i X^i$$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 20

where $g_i = 1$ for 0, 1, 3, 4, 5, 6, 7, 10, 11, 14, 17, 18, 23, 24, and 0 otherwise.

Note.— See IS-GPS-705F for full details on the CNAV parity algorithm.

3.1.1.2.2.2 *Satellite clock correction.* Section 3.1.1.2.1.2 shall apply.

Note.— Additional terms apply to the satellite clock correction for single-frequency L5 and dual-frequency L1 and L5 users as shown in 3.1.1.2.2.5.

3.1.1.2.2.3 *Satellite position.* The current satellite position (X_k, Y_k, Z_k) shall be calculated as shown in Table B L5-5.

Note.— The ephemeris parameters: $t_{os}, \Delta A, \dot{A}, \Delta n_0, \dot{\Delta n}_0, M_{0-n}, e_n, \omega_n, \Omega_{0-n}, \Delta \dot{\Omega}, i_{0-n}, \dot{i}_{0-n}, C_{is-n}, C_{ic-n}, C_{rs-n}, C_{rc-n}, C_{us-n},$ and C_{uc-n} , are provided in CNAV message Types 10 and 11.

3.1.1.2.2.4 Integrity assured user range accuracy (IAURA)

3.1.1.2.2.4.1 *Composite IAURA.* The composite IAURA value shall be the RSS of an elevation-dependent (ED) component and a non-elevation-dependent (NED) component.

$$IAURA = \sqrt{(adjusted\ IAURA_{ED})^2 + IAURA_{NED}^2}$$

3.1.1.2.2.4.2 *Elevation-dependent (ED) accuracy estimate.* An adjusted ED IAURA value (in metres) shall be computed from the upper bound value of the URA_{ED} obtained from message Type 10, Table B-L5-3, and the equation:

$$adjusted\ IAURA_{ED} = URA_{ED}(\sin(E+90))$$

where

E is the satellite elevation angle in degrees ($E \geq 0$)

3.1.1.2.2.4.3 *Non-elevation-dependent (NED) accuracy estimate.* The non-elevation-dependent IAURA value (in metres) shall be computed using the upper bound value of URA_{NED0} and the equation:

$$IAURA_{NED} = URA_{NED0} + URA_{NED1} \times (t - t_{op} + 604,800 \times (WN - WN_{op}))$$

when $t - t_{op} + 604,800 \times (WN - WN_{op}) \leq 93,600$ seconds

and

$$IAURA_{NED} = URA_{NED0} + URA_{NED1} \times (t - t_{op} + 604,800 \times (WN - WN_{op})) + URA_{NED2} \times (t - t_{op} + 604,800 \times (WN - WN_{op}) - 93,600)^2$$

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 21

when $t - t_{top} + 604,800 \times (WN - WN_{op}) > 93,600$ seconds

t = GPS system time

$WN, WN_{op}, t_{top}, URANED0, URANED1, URANED2$ are obtained from message Types 10, 30 to 37, and Table B-L5-4.

3.1.1.2.2.5 Estimated L5 group delay differential for single-frequency users.

Note. — Inter-signal biases for L1/L5 dual-frequency users are corrected via the ionosphere-free pseudo-range described in 3.1.1.2.2.7.

3.1.1.2.2.5.1 For the single-frequency L5 I5 user, the satellite clock time, corrected for the L1/L5 inter-signal bias, shall be as follows:

$$(\Delta t_{SV})_{L5I5} = \Delta t_{SV} - T_{GD} + ISC_{L5I5}$$

3.1.1.2.2.5.2 For the single-frequency L5 Q5 user, the satellite clock time, corrected for the L1/L5 inter-signal bias, shall be as follows:

$$(\Delta t_{SV})_{L5Q5} = \Delta t_{SV} - T_{GD} + ISC_{L5Q5}$$

Note. — T_{GD}, ISC_{L5I5} and ISC_{L5Q5} are provided in CNAV message Type 30.

3.1.1.2.2.6 Ionospheric correction. For L5, the single-frequency ionospheric correction defined in 3.1.1.2.1.4 shall be multiplied by γ_{15} , ($T_{iono,L5} = \gamma_{15} T_{iono,L1}$), where $\gamma_{15} = (f_{L1}/f_{L5})^2 = (1\,575.42/1\,176.45)^2 = (154/115)^2$.

3.1.1.2.2.7 L1/L5 ionospheric correction for dual-frequency users.

3.1.1.2.2.7.1 The ionosphere-free pseudo-range for the dual-frequency (L1 C/A and L5 I5) user shall be as follows:

$$PR = \frac{(PR_{L5I5} - \gamma_{15} PR_{L1C/A}) + c(ISC_{L5I5} - \gamma_{15} ISC_{L1C/A})}{1 - \gamma_{15}} - cT_{GD}$$

where

- PR = pseudo-range corrected for ionospheric effects,
- PR_i = pseudo-range measured on the channel indicated by the subscript,
- ISC_i = inter-signal correction for the channel indicated by the subscript, provided in CNAV message Type 30,
- T_{GD} = L1 P(Y) and L2 P(Y) inter-signal correction, provided in CNAV message Type 30,
- c = speed of light, and
- $\gamma_{15} = (f_{L1}/f_{L5})^2 = (1\,575.42/1\,176.45)^2 = (154/115)^2$.

3.1.1.2.2.7.2 The ionosphere-free pseudo-range for the dual-frequency (L1 C/A and L5 Q5) user shall be as follows:

$$PR = \frac{(PR_{L5Q5} - \gamma_{15} PR_{L1C/A}) + c(ISC_{L5Q5} - \gamma_{15} ISC_{L1C/A})}{1 - \gamma_{15}} - cT_{GD}$$

where

PR, PR_i, ISC_i, T_{GD}, c and γ_{15} are as defined above.

Table B-14. Elements of coordinate systems for L5 CNAV data

$t_k = t - t_{oe}$	Time from ephemeris reference epoch*
$A_0 = A_{REF} + \Delta A$	Semi-major axis at reference time**
$A_k = A_0 + \dot{A}t_k$	Semi-major axis
$n_0 = \sqrt{\frac{\mu}{A_0^3}}$	Computed mean motion
$\Delta n_A = \Delta n_0 + \frac{1}{2}\Delta \dot{n}_0 t_k$	Mean motion difference from computed value
$n_A = n_0 + \Delta n_A$	Corrected mean motion
$M_k = M_0 + n_A t_k$	Mean anomaly
$M_k = E_k - e_n \sin E_k$	Kepler's equation for eccentric anomaly (may be solved by iteration)
$v_k = \tan^{-1} \left\{ \frac{\sin v_k}{\cos v_k} \right\} = \tan^{-1} \left\{ \frac{\sqrt{1 - e^2} \sin E_k / (1 - e \cos E_k)}{(\cos E_k - e) / (1 - e \cos E_k)} \right\}$	True anomaly
$E_k = \cos^{-1} \left\{ \frac{e + \cos v_k}{1 + e \cos v_k} \right\}$	Eccentric anomaly
$\phi_k = v_k + \omega$	Argument of latitude
Second Harmonic Perturbations	
$\delta u_k = C_{us-n} \sin 2\phi_k + C_{uc-n} \cos 2\phi_k$	Argument of latitude correction

3.1.1.3 Aircraft Elements

3.1.1.3.1 GPS Receiver

3.1.1.3.1.1 Reserved

3.1.1.3.1.2 Satellite tracking. The receiver shall provide the capability to continuously track a minimum of four satellites and generate a position solution based upon those measurements.

3.1.1.3.1.3 Doppler shift. The receiver shall be able to compensate for dynamic Doppler shift effects on nominal SPS signal carrier phase and C/A code measurements. The receiver shall compensate for the Doppler shift that is unique to the anticipated application.

3.1.1.3.1.4 Resistance to interference. The receiver shall meet the requirements for resistance to interference as specified in Chapter 3, 3.7.

3.1.1.3.1.5 Application of clock and ephemeris data. The receiver shall ensure that it is using the correct ephemeris and clock data before providing any position solution. The receiver shall monitor the IODC and IODE values, and to update ephemeris and clock databased upon a detected change in one or both of these values. The SPS receiver shall use clock and ephemeris data with corresponding IODC and IODE values for a given satellite.

3.1.1.4 Time

GPS time shall be referenced to a UTC (as maintained by the U.S. Naval Observatory) zero time-point defined as midnight on the night of 5 January 1980/morning of 6 January 1980. The largest unit used in stating GPS time shall be 1 week, defined as 604 800 seconds. The GPS time scale shall be maintained to be within 1 microsecond of UTC (Modulo 1 second) after correction for the integer number of leap seconds difference. The navigation data shall contain the requisite data for relating GPS time to UTC.

3.1.2 Global navigation satellite system (GLONASS) channel of standard accuracy (CSA) (L1/L3)

Note - In this section the term GLONASS refers to all satellites in the constellation. Standards relating only to GLONASS-M satellites are qualified accordingly.

3.1.2.1 Non-Aircraft Elements

3.1.2.1.1 L1OF (L1 OPEN SERVICE FDMA) RF Characteristics

Note. — Additional information on the L1OF RF characteristics is given in the GLONASS Navigational radio signal in bands L1, L2 Interface Control Document (Edition 5.1), dated 2008 (hereinafter referred to as “GLONASS FDMA ICD”).

3.1.2.1.1.1 Carrier frequencies. The nominal values of L1 carrier frequencies shall be as defined by the following expressions:

$$f_{k1} = f_{01} + k\Delta f_1$$

where

Third Edition	Amendment 00	Bhutan Civil Aviation Authority	April 2024
---------------	--------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 24

$K = -7, \dots, 0, 1, \dots, 6$ are carrier numbers (frequency channels) of the signals transmitted by GLONASS satellites in the L1 sub-band;

$$f_{01} = 1\,602 \text{ MHz};$$

$$\Delta f_1 = 0.5625 \text{ MHz}.$$

Carrier frequencies shall be coherently derived from a common on-board time/frequency standard. The nominal value of frequency, as observed on the ground, shall be equal to 5.0 MHz. The carrier frequency of a GLONASS satellite shall be within $\pm 2 \times 10^{-11}$ relative to its nominal value f_k .

Note 1 - The nominal values of carrier frequencies for carrier numbers k are given in Table B-15.

Note 2 - For GLONASS-M satellites, the L2 channel of standard accuracy (CSA) navigation signals will occupy the 1 242.9375 – 1 251.6875 MHz ± 0.511 MHz bandwidth as defined by the following expressions:

$$f_{k2} = f_{02} + k \Delta f_2,$$

$$f_{02} = 1\,246 \text{ MHz};$$

$$\Delta f_2 = 0.4375 \text{ MHz}.$$

For any given value of k the ratio of carrier frequencies of L1 and L2 sub-bands will be equal to:

$$\frac{f_{k2}}{f_{k1}} = \frac{7}{9}$$

Table B-15. L1 carrier frequencies

<i>Carrier number</i>	H_n^A <i>(see 3.2.1.3.4)</i>	<i>Nominal value of frequency in L1 sub-band (MHz)</i>
6	6	1 605.3750
5	5	1 604.8125
4	4	1 604.2500
3	3	1 603.6875
2	2	1 603.1250
1	1	1 602.5625
0	0	1 602.0000
- 1	31	1 601.4375
- 2	30	1 600.8750
- 3	29	1 600.3125
- 4	28	1 599.7500
- 5	27	1 599.1875
- 6	26	1 598.6250
- 7	25	1 598.0625

3.1.2.1.1.2 Carrier phase noise. The phase noise spectral density of the unmodulated carrier shall be such that a phase locked loop of 10 Hz one-sided noise bandwidth provides the accuracy of carrier phase tracking not worse than 0.1 radian (1 sigma).

3.1.2.1.1.3 GLONASS pseudo- random code generation. The pseudo-random ranging code shall be a 511-bit sequence that is sampled at the output of the seventh stage of a 9-stage shift register. The initialization vector to generate this sequence shall be “11111111”. The generating polynomial that corresponds to the 9-stage shift register shall be:

$$G(x) = 1 + x^5 + x^9.$$

3.1.2.1.1.4 Spurious emissions. The power of the transmitted RF signal beyond the GLONASS allocated bandwidth shall not be more than –40 dB relative to the power of the unmodulated carrier.

Note 1- GLONASS satellites launched during 1998 to 2005 and beyond use filters limiting out-of-band emissions to the harmful interference limit contained in Recommendation ITU-R RA.769 for the 1 660 – 1 670 MHz band.

Note 2 - GLONASS satellites launched beyond 2005 use filters limiting out-of-band emissions to the harmful interference limit contained in Recommendation ITU-R RA.769 for the 1 610.6 – 1 613.8 MHz and 1 660 – 1 670 MHz bands.

3.1.2.1.1.5 Correlation loss. The loss in the recovered signal power due to imperfections in the signal modulation and waveform distortion shall not exceed 0.8 dB.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 26

Note - The loss in signal power is the difference between the broadcast power in a 1.022 MHz bandwidth and the signal power recovered by a noise-free, loss-free receiver with 1-chip correlator spacing and a 1.022 MHz bandwidth.

3.1.2.1.2 L1OF (L1 open service FDMA) Data Structure

Note. — Additional information concerning the data structure is given in the GLONASS FDMA ICD.

3.1.2.1.2.1 General. The navigation message shall be transmitted as a pattern of digital data which are coded by Hamming code and transformed into relative code. Structurally, the data pattern shall be generated as continuously repeating super-frames. The super-frame shall consist of the frames and the frames shall consist of the strings. The boundaries of strings, frames and super-frames of navigation messages from different GLONASS satellites shall be synchronized within 2 milliseconds.

3.1.2.1.2.2 Super-frame structure. The super-frame shall have a 2.5-minute duration and shall consist of 5 frames. Within each super-frame a total content of non-immediate information (almanac for 24 GLONASS satellites) shall be transmitted.

Note - Superframe structure with indication of frame numbers in the superframe and string numbers in the frames is shown in Figure B-7.

3.1.2.1.2.3 Frame structure. Each frame shall have a 30-second duration and shall consist of 15 strings. Within each frame the total content of immediate information (ephemeris and time parameters) for given satellite and a part of non-immediate information (almanac) shall be transmitted. The frames 1 through 4 shall contain the part of almanac for 20 satellites (5 satellites per frame) and frame 5 shall contain the remainder of almanac for 4 satellites. The almanac for one satellite shall occupy two strings.

Note - Frame structures are shown in Figures B-8 and B-9.

3.1.2.1.2.4 String structure. Each string shall have a 2-second duration and shall contain binary chips of data and time mark. During the last 0.3 second within this 2-second interval (at the end of each string) the time mark shall be transmitted. The time mark (shortened pseudo-random sequence) shall consist of 30 chips with a time duration for each chip of 10 milliseconds and having the following sequence:

1 1 1 1 1 0 0 0 1 1 0 1 1 1 0 1 0 1 0 0 0 0 1 0 0 1 0 1 1 0.

During the first 1.7 seconds within this 2-second interval (in the beginning of each string) 85 bits of data (each data bit of a 20 milliseconds duration) shall be transmitted in bi-binary format. The numbers of bits in the string shall be increased from right to left. Along with information bits (bit positions 9 through 84) the check bits of Hamming code (KX) (bit positions 1 through 8) shall be transmitted. The Hamming code shall have a code length of 4. The data of one string shall be separated from the data of adjacent strings by time mark (MB). The words of the data shall be registered by MSB ahead. In each string bit position, 85 shall be an idle chip (“0”) and be transmitted first.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 27

3.1.2.1.2.4.1 Strings 1 through 4. The information contained in strings 1 through 4 of each frame shall correspond to the satellite from which it is transmitted. This information shall not be changed within the super-frame.

3.1.2.1.2.4.2 Strings 5 through 15. Strings 5 through 15 of each frame shall contain GLONASS almanac for 4 or 5 satellites. The information contained in the fifth string shall be repeated in each frame of the superframe.

3.1.2.1.3 L1OF (L1 open service FDMA) Data Content

Note. — Additional information concerning the data content is given in the *GLONASS FDMA ICD*.

3.1.2.1.3.1 Ephemeris and time parameters. The ephemeris and time parameters shall be as follows:

m = the string number within the frame;

t_k = the time referenced to the beginning of the frame within the current day. It is calculated according to the satellite time scale. The integer number of hours elapsed since the beginning of the current day is registered in the 5 MSBs. The integer number of minutes elapsed since the beginning of the current hour is registered in the next 6 bits. The number of 30-second intervals elapsed since the beginning of the current minute is registered in the one LSB. The beginning of the day according to the satellite time scale coincides with the beginning of the recurrent superframe;

t_b = the time interval within the current day according to UTC(SU) + 03 hours 00 min. The immediate data transmitted within the frame are referred to the middle of t_b . Duration of the time interval and therefore the maximum value of t_b depends on the value of the flag P1;

$\gamma_n(t_b)$ = the relative deviation of predicted carrier frequency value of n-satellite from the nominal value at the instant t_b , i.e.

$$\gamma_n(t_b) = \frac{f_n(t_b) - f_{Hn}}{f_{Hn}}$$

where

$f_n(t_b)$ = the forecast frequency of n-satellite clocks at an instant t_b ;

f_{Hn} = the nominal value of frequency of n-satellite clocks;

$\tau_n(t_b)$ = the correction to the n-satellite time t_n relative to GLONASS time t_c at an instant t_b , i.e. $\tau_n(t_b) = t_c(t_b) - t_n(t_b)$;

$x_n(t_b), y_n(t_b), z_n(t_b)$ = the coordinates of n-satellite in PZ-90 coordinate system at an instant t_b ;

$\dot{x}_n(t_b), \dot{y}_n(t_b), \dot{z}_n(t_b)$ = the velocity vector components of n-satellite in PZ-90 coordinate system at an instant t_b ;

$\ddot{x}_n(t_b), \ddot{y}_n(t_b), \ddot{z}_n(t_b)$ = the acceleration components of n-satellite in PZ-90 coordinate system at an instant t_b , which are caused by effect of sun and moon;

- E_n = an indication of the “age” of the immediate information, i.e. a time interval elapsed since the instant of its calculation (uploading) until the instant t_b for n-satellite;
- B_n = the health flag. Values greater than 3 indicate the fact of malfunction of given satellite;
- $P1$ = a flag indicating the time interval between the current and previous value of the t_b parameters in minutes as shown:

P1	Time interval between adjacent values of t_b in minutes
0	0
1	30
10	45
11	60

- $P2$ = a flag indicating whether the value of t_b is odd or even. A value of “1” indicates a 30-minute interval of service information transmit ($t_b = 1, 3, 5 \dots$), a value of “0” indicates a 60-minute interval of service information transmit ($t_b = 2, 6, 10 \dots$);
- $P3$ = a flag indicating the number of satellites for which an almanac is transmitted within a given frame. “1” corresponds to 5 satellites and “0” corresponds to 4 satellites; and
- $\Delta\tau_n$ = the time difference between the navigation RF signal transmitted in L2 sub-band and navigation RF signal transmitted in L1 sub-band by given satellite:

$$\Delta\tau_n = t_{f2} - t_{f1}$$

where t_{f1} , t_{f2} are the equipment delays in L1 and L2 sub-bands respectively, expressed in units of time.

3.1.2.1.3.2 Ephemeris and time parameters. The ephemeris and time parameters shall be as indicated in Table B-17. For the words for which numeric values may be positive or negative, the MSB shall be the sign bit. The chip “0” shall correspond to the “+” sign and the chip “1” shall correspond to the “-” sign.

3.1.2.1.3.3 Arrangement of the ephemeris and time parameters. Arrangements of the ephemeris and time parameters within a frame shall be as indicated in Table B-17.

3.1.2.1.3.4 Almanac parameters. The almanac parameters shall be as follows:

- A = an index showing relation of this parameter with the almanac;
- M_n^A = an index of the modification of n^A -satellite: “00” indicates GLONASS satellite, and “01” indicates GLONASS-M satellite;
- τ_c = the GLONASS time scale correction to UTC(SU) time. The correction τ_c is given at the instant of day N^A ;
- N^A = the calendar day number within the 4-year period beginning since the leap year. The correction τ_c and other almanac data (almanac of orbits and almanac of phases) relate to this day number;
- n^A = the slot number occupied by n -satellite;
- H_n^A = the channel number of a carrier frequency of n^A -satellite (Table B-16);
- λ_n^A = the longitude of the first (within the N^A -day) ascending node of n^A -satellite orbit in PZ-90 coordinate system;
- $t_{\lambda_n}^A$ = the time of the first ascending node passage of n^A -satellite within N^A -day;

Table B-16. Ephemeris and time parameters

<i>Parameter</i>	<i>Number of bits</i>	<i>Scale factor (LSB)</i>	<i>Effective range</i>	<i>Units</i>
m	4	1		dimensionless
	5	1	0 to 23	hours
t_k	6	1	0 to 59	minutes
	1	30	0 or 30	seconds
t_b	7	15	15...1 425	minutes
$\gamma_n(t_b)$	11	2^{-40}	$\pm 2^{-30}$	dimensionless
$\tau_n(t_b)$	22	2^{-30}	$\pm 2^{-9}$	seconds
$x_n(t_b), y_n(t_b), z_n(t_b)$	27	2^{-11}	$\pm 2.7 \times 10^4$	km
$\dot{x}_n(t_b), \dot{y}_n(t_b), \dot{z}_n(t_b)$	24	2^{-20}	± 4.3	km/second
$\ddot{x}_n(t_b), \ddot{y}_n(t_b), \ddot{z}_n(t_b)$	5	2^{-30}	$\pm 6.2 \times 10^{-9}$	km/second ²
E_n	5	1	0 to 31	days
B_n	3	1	0 to 7	dimensionless
P1	2	—————	as detailed in 3.1.2.1.3.1	—————
P2	1	1	0; 1	dimensionless
P3	1	1	0; 1	dimensionless
$\Delta\tau_n$	5	2^{-30}	$\pm 13.97 \times 10^{-9}$	seconds

Table B-17. Arrangements of the ephemeris and time parameters within the frame

<i>Parameter</i>	<i>Number of bits</i>	<i>String number within the frame</i>	<i>Bit number within the frame</i>
m	4	1...15	81 – 84
t_k	12	1	65 – 76
t_b	7	2	70 – 76
$\gamma_n(t_b)$	11	3	69 – 79
$\tau_n(t_b)$	22	4	59 – 80
$x_n(t_b)$	27	1	9 – 35
$y_n(t_b)$	27	2	9 – 35
$z_n(t_b)$	27	3	9 – 35
$\dot{x}_n(t_b)$	24	1	41 – 64
$\dot{y}_n(t_b)$	24	2	41 – 64
$\dot{z}_n(t_b)$	24	3	41 – 64
$\ddot{x}_n(t_b)$	5	1	36 – 40
$\ddot{y}_n(t_b)$	5	2	36 – 40
$\ddot{z}_n(t_b)$	5	3	36 – 40
E_n	5	4	49 – 53
B_n	3	2	78 – 80
P1	2	1	77 – 78
P2	1	2	77
P3	1	3	80
$\Delta\tau_n$	5	4	54 – 58

Δi_n^A = the correction to the mean value of inclination of n^A -satellite at instant of $t_{\lambda_n}^A$ (mean value of inclination is equal to 63 degrees);

ΔT_n^A = the correction to the mean value of Draconian period of the n^A -satellite at the instant of $t_{\lambda_n}^A$ (mean value of Draconian period T is equal to 43 200 seconds);

$\Delta \dot{T}_n^A$ = the rate of change of Draconian period of n^A -satellite;

ε_n^A = the eccentricity of n^A -satellite at instant of $t_{\lambda_n}^A$;

ω_n^A = the argument of perigee of n^A -satellite at the instant of $t_{\lambda_n}^A$;

τ_n^A = the coarse value of n^A -satellite time correction to GLONASS time at instant of $t_{\lambda_n}^A$;

C_n^A = a generalized “unhealthy flag” of n^A -satellite at instant of almanac upload almanac of orbits and phases. When $C_n = 0$, this indicates that n -satellite is non-operational. When $C_n = 1$, this indicates that n -satellite is operational.

3.1.2.1.3.5 Partition and coding of almanac parameters. The GLONASS almanac, transmitted within the super-frame, shall be partitioned over the super-frame, as indicated in Table B-21. The numeric values of almanac parameters shall be positive or negative. The MSB shall be the sign bit, the chip “0” shall correspond to the “+” sign, and the chip “1” shall correspond to the “-” sign. The almanac parameters shall be coded as indicated in Table B-18.

3.1. 2.1.3.6 Arrangement of the almanac parameters. Arrangement of the almanac words within the frame shall be as indicated in Table B-19.

3.1.2.1.4 Content and Structure of additional data Transmitted by GLONASS-M satellites in L1OF (L1 open service FDMA)

Note. — Additional information concerning the data content and structure is given in the GLONASS FDMA ICD.

3.1.2.1.4.1 Letter designation of additional data. In addition to the GLONASS data, GLONASS-M satellites shall transmit the following additional data as indicated in Table B-20:

n = an index of the satellite transmitting the given navigation signal : it corresponds to a slot number within GLONASS constellation;

I_n = health flag for n - th satellite : “0” indicates the n - th satellite is healthy, “1” indicates the malfunction of the n - the satellite;

$B1$ = coefficient to determine $\Delta UT1$: it is equal to the difference between UT1 and UTC at the beginning of the day (N^A), expressed in seconds;

$B2$ = coefficient to determine $\Delta UT1$: it is equal to the daily change of the difference $\Delta UT1$ (expressed in seconds for a)mean sun day

These coefficients shall be used to transform between UTC(SU) and UT1 :

$$\Delta UT1 = UTC(SU) - UT1,$$

where

UT1 — Universal Time referenced to the Mean Greenwich Meridian (taking account of Pole motion),

UTC(SU) — Coordinated Universal Time of the Russian Federation State Standard,

$$\Delta UT1 = B1 + B2 \times (N_T - N^A),$$

KP	UTC second correction data
00	No UTC correction at the end of the current quarter
01	UTC correction by plus 1 s at the end of the current quarter
11	UTC correction by minus 1 s at the end of the current quarter

Note. — GLONASS system timescale correction is usually performed once a year at midnight 00 hours 00 minutes 00 seconds in accordance with the early notification of the International Time Bureau (BIH/BIPM) at the end of a quarter:

from 31 December to 1 January — first quarter,

from 31 March to 1 April — second quarter,

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 32

from 30 June to 1 July — third quarter,

from 30 September to 1 October — fourth quarter.

N_T — current date, calendar number of the day within the four-year interval starting from 1 January in a leap year;

Note. — An example of N_T transformation into the common form of current data information (dd/mm/yy) is presented in Attachment D, 4.1.2.7.1.

N_4 — four-year interval number starting from 1996;

F_T — a parameter that provides the predicted satellite user range accuracy at time t_b . Coding is as indicated in Table B-17-B;

M — type of satellite transmitting the navigation signal. 00 refers to a GLONASS satellite; 01 refers to a GLONASS-M satellite;

P_4 — flag to show that updated ephemeris parameters are present. “1” indicates that an updated ephemeris or frequency/time parameters have been uploaded by the control segment;

Note.— Updated ephemeris or frequency/time information is transmitted in the next interval after the end of the current interval t_b .

P — technological parameter of control segment indicating the satellite operation mode in respect of time parameters:

00 — τ_c parameter relayed from control segment, τ_{GPS} parameter relayed from control segment;

01 — τ_c parameter relayed from control segment, τ_{GPS} parameter calculated on-board the GLONASS-M satellite;

10 — τ_c parameter calculated on-board the GLONASS-M satellite; τ_{GPS} parameter relayed from control segment;

11 — τ_c parameter calculated on-board the GLONASS-M satellite; τ_{GPS} parameter calculated on-board the GLONASS-M satellite;

τ_{GPS} — correction to GPS time relative to GLONASS time:

$$T_{GPS} - T_{GL} = \Delta T + \tau_{GPS},$$

where

ΔT is the integer part, and τ_{GPS} is the fractional part of the difference between the system timescales expressed in seconds.

Note.— The integer part ΔT is determined from the GPS navigation message by the user receiver.

M^A — type of satellite n^A : coding “00” indicates a GLONASS satellite, coding “01” indicates a GLONASS-M satellite.

3.1.2.1.4.2 Additional data parameters. Additional data parameters are defined in Tables B-18 to B-20.

3.1.2.1.4.3 Location of additional data words within GLONASS-M navigation message. The required location of additional data words within the GLONASS-M navigation message is defined in Table B-20.

Table B-18. Additional data parameters

<i>Parameter</i>	<i>No. of bits</i>	<i>Scale factor (LSB)</i>	<i>Effective range</i>	<i>Units</i>
n	5	1	0 to 31	Dimensionless
l_n	1	1	0; 1	Dimensionless
B1	11	2^{-10}	± 0.9	seconds
B2	10	2^{-16}	$(-4.5 \text{ to } 3.5) \times 10^{-3}$	s/mean sun day
KP	2	1	0 to 3	Dimensionless
N_T	11	1	0 to 1 461	days
N_4	5	1	1 to 31	four-year interval
F_T	4		See table B-19	
M	2	1	0 to 3	Dimensionless
P4	1	1	0; 1	Dimensionless
P	2	1	00,01,10,11	Dimensionless
τ_{GPS}	22	2^{-30}	$\pm 1.9 \times 10^{-3}$	seconds
M_n^A	2	1	0 to 3	Dimensionless

$t_{r_n^A}$	10	6, 8, 10, 12, 14	63 – 72
C_n^A	1	6, 8, 10, 12, 14	80

Note.— String numbers of the first four frames within superframe are given. There are no almanac parameters in 14th and 15th strings of 5th frame.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 36

3.1.2.1.5 L1OC, L3OC RF CHARACTERISTICS

Note. — Additional information concerning the RF characteristics is given in the GLONASS CDMA ICD General Description of CDMA Signal System, Edition 1.0, dated 2016 (hereinafter referred to as “GLONASS CDMA ICD General Description”); in the GLONASS CDMA ICD L1 band; and in the GLONASS CDMA ICD L3 band.

3.1.2.1.5.1 The L1OC signal shall contain L1OCd data and L1OCp pilot components of equal power levels. These components shall be obtained by chip-by-chip time-division multiplexing of two pseudo random noise sequences. The L1OC signal shall be in phase quadrature with the L1SC signal. L1OC leads L1SC by $\pi/2$ radians as shown in Figure B-11A.

Note. — The L1SC signal is a CDMA secured service navigation signal in the L1 frequency band and is not used in aviation.

3.1.2.1.5.2 The L3OC signal shall contain L3OCd data and L3OCp pilot components of equal power levels. These components shall occupy phase quadratures I and Q, respectively. L3OCd leads L3OCp by $\pi/2$ radians as shown in Figure B-11A.

3.1.2.1.5.3 *Carrier phase noise.* The phase noise spectral density of the unmodulated carrier shall be such that a phase locked loop of 10 Hz one-sided noise bandwidth shall be able to track the carrier to accuracy no worse than 0.01 radians rms.

3.1.2.1.5.4 *Spurious emissions.* The power of the transmitted RF signal beyond the GLONASS allocated bandwidth shall not be more than –40 dB relative to the power of the unmodulated carrier.

Note 1.— The GLONASS allocated bandwidths are L1 (1 592.9 – 1 610 MHz), L2 (1 237.8 – 1 256.8 MHz) and L3 (1 190.35 – 1 212.23 MHz).

Note 2.— GLONASS satellites use filters limiting out-of-band emissions to the harmful interference limit contained in Recommendation ITU-R RA.769 for the 1 610.6 – 1 613.8 MHz and 1 660 – 1 670 MHz bands.

3.1.2.1.5.5 *Correlation loss.* The loss in the recovered signal power due to imperfections in the signal modulation and waveform distortion shall not exceed 0.6 dB.

Note. — The loss in signal power is the difference between the broadcast power in the specified bandwidth and the signal power recovered by a noise-free, loss-free receiver with 1-chip correlator spacing and an RF front-end with the same bandwidth.

3.1.2.1.6 L1OC, L3OC DATA STRUCTURE

Note. — Additional information concerning the data structure is given in the GLONASS CDMA ICD General Description; in the GLONASS CDMA ICD L1 band; and in the GLONASS CDMA ICD L3 band.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 37

3.1.2.1.6.1 *General.* The GLONASS CDMA navigation message shall be transmitted as a variable sequence of strings. Strings shall comprise service and data fields (separate bits or groups of bits containing specific parameters).

Note. — A pseudoframe is a set of strings of immediate and non-immediate data starting with the three strings of ephemeris and clock data (immediate data). The remaining strings of a pseudoframe contain non-immediate data.

3.1.2.1.6.2 *Service fields.* The structure of a service section shall be the same for each type of signal and include preamble, type of the string, time of the beginning of the string (TS), satellite ID number, signal parameters and cyclic redundancy check (CRC) bits to check the integrity of the string data.

3.1.2.1.6.3 *Data fields.* The structure of data fields shall depend on the string type. Each type of string shall contain a complete individual block of data with the exception of orbit and clock data, which occupies three types of strings and shall be transmitted as a continuous packet.

Note. — The message design may evolve together with future evolutions of GLONASS. This evolution may involve the inclusion of additional new string types, which can either contain new data types or modify the existing string types.

3.1.2.1.6.4 L1OC message characteristics

3.1.2.1.6.4.1 The L1OCd navigation message shall be transmitted at 125 bits/s. The message shall consist of 250-bit strings of 2-second duration as well as of 125- and 375-bit anomalous strings of 1- and 3-second duration, respectively.

3.1.2.1.6.4.2 *L1OCd nominal string structure.* Each L1OCd nominal string shall consist of 50-bit service fields, a 184-bit data field and a 16-bit CRC service field as shown in Figure B-11B. Transmission of a string shall start with bit 1 (the first bit of the preamble and end with bit 250 (last bit of CRC)).

3.1.2.1.6.4.3 *L1OCd service fields* shall be as shown in Table B-24.

Table B-24. Parameters of L1OCd service fields

<i>Field</i>	<i>Number of bits</i>	<i>Least significant bit</i>	<i>Value range</i>	<i>Unit</i>	<i>Description</i>
Preamble	12	1	010111110001	-	Constant time stamp
Type	6	1	0 – 63	-	Type of a current string
j	6	1	0 – 63	-	ID number of a satellite that transmits this navigation message. SV ID number “0” is reserved and can only be enabled upon termination of combined use of GLONASS CDMA and FDMA signals.
H ^h	1	1	0, 1	-	healthy (“0”) or unhealthy (“1”) navigation signal
i	1	1	0, 1	-	validity (“0”) or invalidity (“1”) of the data transmitted in the current string
P1	4	Ground control call. This field is not used by user receivers.			
P2	1	Attribute of SV orientation regime: SV is Sun-pointing (“0”) or performs noon/midnight turn manoeuvre (“1”)			
KP	2	1	00, 01, 10, 11	-	Indication of the expected UTC(SU) correction at the end of current quarter on GMT. UTC(SU) corrections shall result in the corresponding corrections of L1OCd time: 00 – no correction planned; 01 – day length is increased by 1 s; 10 – correction decision is pending; 11 – day length is reduced by 1 s.
A	1	1	0, 1	-	Indication of the expected L1OCd signal time correction at the end of the next string: A = 0 – no correction is planned. A = 1 – correction is planned. The combination of A = 1 and KP = 11 in the current string denotes that the next string will be a Type 1 anomalous string of 1 s duration. The combination of A = 1 and KP = 01 in the current string denotes that the next string will be a Type 2 anomalous string of 3 s duration.
TS	16	1	0 – 43199	2 s	Time stamp digits expressed in 2-second intervals within a current day in L1OCd time.
CRC	16	1	Check bits of the cyclic code		

3.1.2.1.6.4.4 *L1OCd anomalous strings.* Anomalous strings shall be indicated by string Types 1 and 2. Strings of Type 1 shall be used to indicate the leap second corrections of L1OCd signal time when a day’s length is reduced by 1 s. Strings of Type 1 shall consist of 50-bit service fields, a 59-bit data field and a 16-bit CRC service field as shown in Figure B-7C. Strings of Type 2 shall be used to indicate the leap second corrections of L1OCd signal time when a day’s length is increased by 1 s. Strings of Type 2 shall consist of 50-bit service fields, a 301-bit data field and a 24-bit CRC service field as shown in Figure B-11D.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 39

3.1.2.1.6.4.5 *L1OCd nominal strings CRC*. The CRC (250,234) generator polynomial shall have the following form:

$$g(X) = 1 + X + X^5 + X^6 + X^8 + X^9 + X^{10} + X^{11} + X^{13} + X^{14} + X^{16}.$$

A 234-bit data block shall be delivered to the encoder's input (starting with the 1st bit of the preamble and ending with the 184th bit of the data field). At the encoder's output, a 250-bit encoded block shall be generated by adding 16 check bits.

3.1.2.1.6.4.6 *L1OCd anomalous string Type 1 CRC*. CRC (125,109) shall be used in L1OCd Type 1 strings. It shall be generated similarly to code (250,234) except for the number of bits delivered to the input (109 instead of 234).

3.1.2.1.6.4.7 *L1OCd anomalous strings Type 2 CRC*. CRC (375,351) shall be used in L1OCd Type 2 strings. The CRC (375,351) generator polynomial shall have the following form:

$$g(X) = 1 + X + X^3 + X^4 + X^5 + X^6 + X^7 + X^{10} + X^{11} + X^{14} + X^{17} + X^{18} + X^{23} + X^{24}.$$

A 351-bit data block shall be delivered to the encoder's input (starting with the 1st bit of the preamble and ending with the 301st bit of the data field). At the encoder's output, a 375-bit encoded block shall be generated by adding 24 check bits.

3.1.2.1.6.5 L3OC message characteristics

3.1.2.1.6.5.1 The L3OCd navigation message shall be transmitted at 100 bits/s. The message shall consist of 300-bit strings of 3-second duration as well as of 200- and 400-bit anomalous strings of 2- and 4-second duration, respectively.

3.1.2.1.6.5.2 *L3OCd strings structure*. Each L3OCd nominal string shall consist of 57-bit service fields, a 219-bit long data field and 24-bit long CRC service field, as shown in Figure B-12A. Transmission of a string shall start with bit 1 (the first bit of the preamble) and end with bit 300 (the last bit of CRC).

3.1.2.1.6.5.3 *L3OCd service fields* shall be as shown in Table B-25.

Table B-25. Parameters of L3OCd service fields

<i>Field</i>	<i>Number of bits</i>	<i>Least significant bit</i>	<i>Value range</i>	<i>Unit</i>	<i>Description</i>
Preamble	20	1	00000100100101001110	-	Constant time stamp
Type	6	1	0 – 63	-	Type of a current string
TS	15	1	0 – 28799	3 s	Time stamp digits expressed in 3-second intervals within a current day in L3OCd time.
j	6	1	0 – 63	-	ID number of a satellite that transmits this navigation message. SV ID number “0” is reserved, and can only be enabled upon termination of combined use of GLONASS CDMA and FDMA signals.
<i>H</i>	1	1	0, 1	-	healthy (“0”) or unhealthy (“1”) navigation signal
<i>i</i>	1	1	0, 1	-	validity (“0”) or invalidity (“1”) of the data transmitted in the current string
P1	4	Ground control call. This field is not used by user receivers.			
P2	1	Attribute of SV orientation regime: SV is Sun-pointing (“0”) or performs noon/midnight turn manoeuvre (“1”)			
KP	2	1	00, 01, 10, 11	-	Indication of the expected UTC(SU) correction at the end of current quarter on GMT. UTC(SU) corrections shall result in the corresponding corrections of L3OCd time: 00 – no correction planned; 01 – day length is increased by 1 s; 10 – correction decision is pending; 11 – day length is reduced by 1 s.
A	1	1	0, 1	-	Indication of the expected L3OCd signal time correction at the end of the next string: A = 0 – no correction is planned. A = 1 – correction is planned. The combination of A = 1 and KP = 11 in the current string denotes that the next string will be a Type 1 anomalous string of 1 s duration. The combination of A = 1 and KP = 01 in the current string denotes that the next string will be a Type 2 anomalous string of 3 s duration.
CRC	24	1	Check bits of the cyclic code		

3.1.2.1.6.5.4 *L3OCd anomalous strings*. Anomalous strings shall be indicated by strings Types 1 and 2. Strings of Type 1 shall be used to indicate the leap second corrections of L3OCd signal time when a day’s length is reduced by 1 s. Strings of Type 1 shall consist of 57-bit service fields, a 119-bit data field and a 24-bit CRC service field, as shown in Figure B-12B. Strings of Type 2 shall be used to indicate the leap second

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 41

corrections of L3OCd signal time when a day's length is increased by 1 s. Strings of Type 2 shall consist of 57+20-bit service fields, a 299-bit data field and a 24-bit CRC service field as shown in Figure B-12C.

3.1.2.1.6.5.5 *L3OCd nominal strings CRC*. The CRC (300,276) generator polynomial shall have the following form:

$$g(X) = 1 + X + X^3 + X^4 + X^5 + X^6 + X^7 + X^{10} + X^{11} + X^{14} + X^{17} + X^{18} + X^{23} + X^{24}.$$

A 276-bit data block shall be delivered to the encoder's input (starting with the 1st bit of the preamble and ending with the 219th bit of the data field). At the encoder's output, a 300-bit encoded block shall be generated by adding 24 check bits.

3.1.2.1.6.5.6 *L3OCd anomalous string Type 1 CRC*. CRC (200,176) shall be used in L3OCd Type 1 strings. It shall be generated similarly to code (300,276) except for the number of bits delivered to the input (176 instead of 276).

3.1.2.1.6.5.7 *L3OCd anomalous string Type 2 CRC*. CRC (400,376) shall be used in L3OCd Type 2 strings. It shall be generated similarly to code (300,276) except for the number of bits delivered to the input (376 instead of 276).

3.1.2.1.7 *L1OC, L3OC DATA CONTENT*

Note. — Additional information concerning the data content is given in the *GLONASS CDMA ICD General Description*; in the *GLONASS CDMA ICD L1 band*; and in the *GLONASS CDMA ICD L3 band*.

3.1.2.1.7.1 L1OCd navigation messages shall contain the data in accordance with the list of string types shown in Table B-26.

Note. — Additional information concerning the data content of the L1OCd service and data fields is given in the *GLONASS CDMA ICD L1 band*.

Table B-26. Types of L1OCd strings and their content

<i>String type</i>	<i>Content</i>
10, 11, 12	Immediate data (ephemeris, time, health flags, F_E , F_T)
20	Almanac
25	Earth rotation parameters, ionospheric model parameters, UTC(SU) and international atomic time (TAI) offset model parameters.
16	SV attitude parameters during noon/midnight turn manoeuvre
31, 32	Long-term dynamic model parameters
50	International Satellite System for Search and Rescue (COSPAS–SARSAT) notices of receipt
60	Text messages
0	For technological tasks. Not used by user receivers.
1	Anomalous string used at the moment of leap second correction (-1 s)
2	Anomalous string used at the moment of leap second correction (+1 s)
<p><i>Note.— String Types 10, 11 and 12 compose a data packet; therefore, string Type 11 always follows string Type 10 and string Type 12 always follows string Type 11.</i></p>	

3.1.2.1.7.2 L3OCd navigation messages shall contain the data in accordance with the list of string types shown in Table B-27.

Note.— Additional information concerning the data content of the L3OCd service and data fields is given in the GLONASS CDMA ICD L3 band.

Table B-27. Types of L3OCd strings and their content

<i>String type</i>	<i>Content</i>
10, 11, 12	Immediate data (ephemeris, time, health flags, F_E , F_T)
20	Almanac
25	Earth rotation parameters, ionospheric model parameters, UTC(SU) and international atomic time (TAI) offset model parameters.
16	SV attitude parameters during noon/midnight turn manoeuvre
31, 32	Long-term dynamic model parameters
60	Text messages
0	For technological tasks. Not used by user receivers.
1	Anomalous string used at the moment of leap second correction (-1 s)
2	Anomalous string used at the moment of leap second correction (+1 s)
<p><i>Note.— String Types 10, 11 and 12 compose a data package; therefore, string Type 11 always follows string Type 10 and string Type 12 always follows string Type 11.</i></p>	

3.1.2.1.7.3 *Accuracy factor fields F_E , F_T .* Fields F_E and F_T shall contain equivalent pseudo-range errors (σ) related to the ephemeris and clock of transmitting satellite. Table B-28 shows values of F_E and F_T and the corresponding errors.

Table B-28. Ephemeris and time accuracy factors

F_E, F_T	-15	-14	-13	-12	-11	-10	-9	-8	-7	-6	-5	-4
σ, m	0.01	0.02	0.03	0.04	0.06	0.08	0.1	0.15	0.2	0.3	0.4	0.6
F_E, F_T	-3	-2	-1	0	1	2	3	4	5	6	7	8
σ, m	0.7	0.8	0.9	1	2	2.5	4	5	7	10	12	14
F_E, F_T	9	10	11	12	13	14	15					
σ, m	16	32	64	128	256	512	not defined					

3.1.2.1.7.4 The maximum interval of updating immediate data (string Types 10, 11 and 12) shall be 30 minutes. Considering that various types of non-immediate data are updated at various intervals, the maximum update interval for all non-immediate data shall be 48 hours.

Note. — Long-term dynamic model parameters enable the usage of immediate data to propagate the orbit for a 4-hour interval.

3.1.2.2 Definitions of Protocols for Data Application

Note - This section defines the inter-relationships of the data broadcast message parameters. It provides definitions of parameters that are not transmitted, but are used by either or both non-aircraft and aircraft elements, and that define terms applied to determine the navigation solution and its integrity.

Table B-29. Parity checking algorithm

b85, b84, ..., b10, b9 are the data bits (position 9 to 85 in the string);

$\beta_1, \beta_2, \dots, \beta_8$ are the check bits of the Hamming code (positions 1 to 8 in the string);

$c_1, c_2, \dots, c_7, c_T$ are the checksums generated using the following:

$$c_1 = \beta_1 \oplus [\sum_i b_i]_{\text{mod } 2}$$

$$i = 9, 10, 12, 13, 15, 17, 19, 20, 22, 24, 26, 28, 30, 32, 34, 35, 37, 39, 41, 43, 45, 47, 49, 51, 53, 55, 57, 59, 61, 63, 65, 66, 68, 70, 72, 74, 76, 78, 80, 82, 84.$$

$$c_2 = \beta_2 \oplus [\sum_j b_j]_{\text{mod } 2}$$

$$j = 9, 11, 12, 14, 15, 18, 19, 21, 22, 25, 26, 29, 30, 33, 34, 36, 37, 40, 41, 44, 45, 48, 49, 52, 53, 56, 57, 60, 61, 64, 65, 67, 68, 71, 72, 75, 76, 79, 80, 83, 84.$$

$$c_3 = \beta_3 \oplus [\sum_k b_k]_{\text{mod } 2}$$

$$k = 10, 11, 12, 16, 17, 18, 19, 23, 24, 25, 26, 31, 32, 33, 34, 38, 39, 40, 41, 46, 47, 48, 49, 54, 55, 56, 57, 62, 63, 64, 65, 69, 70, 71, 72, 77, 78, 79, 80, 85.$$

$$c_4 = \beta_4 \oplus [\sum_l b_l]_{\text{mod } 2}$$

$$l = 13, 14, 15, 16, 17, 18, 19, 27, 28, 29, 30, 31, 32, 33, 34, 42, 43, 44, 45, 46, 47, 48, 49, 58, 59, 60, 61, 62, 63, 64, 65, 73, 74, 75, 76, 77, 78, 79, 80.$$

$$c_5 = \beta_5 \oplus [\sum_m b_m]_{\text{mod } 2}$$

$$m = 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 81, 82, 83, 84, 85.$$

$$c_6 = \beta_6 \oplus [\sum_n b_n]_{\text{mod } 2}$$

$$n = 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65.$$

$$c_7 = \beta_7 \oplus [\sum_p b_p]_{\text{mod } 2}$$

$$p = 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85.$$

$$c_T = [\sum_q \beta_q]_{\text{mod } 2} \oplus [\sum_r b_r]_{\text{mod } 2}$$

$$q = 1, 2, 3, 4, 5, 6, 7, 8$$

$$r = 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85.$$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 45

3.1.2.2.1 Parity checking algorithm for FDMA data verification. The algorithm shown in Table B-29 and as detailed below is used to detect and correct an error of 1 bit within the string and to detect an error of 2 or more bits within a string.

3.1.2.2.1.1 Each string includes the 85 data bits where the 77 MSBs are data chips ($b_{85}, b_{84}, \dots, b_{10}, b_9$), and the 8 LSBs are the check bits of Hamming code length of 4 ($\beta_8, \beta_7, \dots, \beta_2, \beta_1$).

3.1.2.2.1.2 To correct 1-bit errors within the string the following checksums are generated: (c_1, c_2, \dots, c_7), and to detect 2-bit errors (or more -even-number-of-bits errors) a checksum c_Σ is generated, as shown in Table B-29. The following is used for correcting single errors and detecting multiple errors:

- i. A string is considered correct if all checksums (c_1, \dots, c_7 , and c_Σ) are equal to “0”, or if only one of the checksums (c_1, \dots, c_7) is equal to “1” and c_Σ is equal to “1”.
- ii. If two or more of the checksums (c_1, \dots, c_7) are equal to “1” and c_Σ is equal to “1”, then character “ $b_{i_{cor}}$ ” is corrected to the opposite character in the following bit position:

$$“i_{cor}” = c_7 c_6 c_5 c_4 c_3 c_2 c_1 + 8 - K, \text{ provided that } “i_{cor}” \leq 85,$$

where “ $c_7 c_6 c_5 c_4 c_3 c_2 c_1$ ” is a binary number generated from the checksums (c_1, \dots, c_7) with c_1 being the LSB and c_7 being the MSB. K is the ordinal number of the most significant checksum not equal to “0”.

If $i_{cor} > 85$, then there is an odd number of multiple errors, and the data shall be rejected.

- iii. If at least one of the checksums (c_1, \dots, c_7) is equal to “1” and c_Σ is equal to “0”, or if all checksums (c_1, \dots, c_7) are equal to “0” but c_Σ is equal to “1”, then there are multiple errors and the data shall be rejected.

3.1.2.2.2 Satellite clock Correction Parameters

3.1.2.2.2.1 GLONASS system time shall be determined using FDMA data as:

$$t_{GLONASS} = t_k + \tau_n(t_b) - \gamma_n(t_b) (t_k - t_b)$$

where $t_k, \tau_n(t_b), \gamma_n(t_b)$ are parameters described in 3.1.2.1.3.1.

3.1.2.2.2.2 GLONASS system time shall be determined using CDMA data as:

$$t_{GLONASS} = t_k + \tau_n(t_b) - \gamma_n(t_b) (t_k - t_b)$$

where $t_k, \tau_n(t_b), \gamma_n(t_b)$ are parameters described in 3.1.2.1.3.1.

3.1.2.2.2.2 GLONASS system time shall be determined using CDMA data as:

$$\Delta t_b = \frac{T_{ST[signal]}^j + \tau^j(t_b) + \tau_c(t_b) - t_b - \left\langle \left\langle \frac{T_{ST[signal]}^j + \tau^j(t_b) + \tau_c(t_b) - t_b}{86400} \right\rangle \right\rangle \cdot 86400}{1 + \gamma^j(t_b) - \dot{\tau}_c(t_b)}$$

where

$T_{ST[signal]}^j$ is the signal time of received signal from satellite j and
 $\tau^j(t_b), \gamma^j(t_b), \beta^j(t_b), \tau_c(t_b), \dot{\tau}_c(t_b)$ are parameters transmitted in CDMA signals within string of Types 10, 11 and 12 as shown in Table B-26 and Table B-27.

3.1.2.2.2.3 GLONASS system time offset to National Time Service of Russia (UTC(SU)) shall be determined using FDMA data as::

$$t_{UTC(SU)} = t_{GLONASS} + \tau_c - 03 \text{ hours } 00 \text{ minutes}$$

where

τ_c is a parameter described in 3.1.2.1.3.4 and

03 hours 00 minutes is continuous time shift caused by difference between Moscow time and Greenwich time.

3.1.2.2.2.4 GLONASS system time offset to UTC(SU) shall be determined using CDMA data as:

$$t_{UTC(SU)} = \text{mod}_{86400}[t_{GLONASS} + \tau_c(t_b) + \Delta t_b \cdot \dot{\tau}_c(t_b) - 10800]$$

$$\Delta t_b = \frac{t_{GLONASS} + \tau_c(t_b) - t_b - \left\langle \left\langle \frac{t_{GLONASS} + \tau_c(t_b) - t_b}{86400} \right\rangle \right\rangle \cdot 86400}{1 - \dot{\tau}_c(t_b)}$$

where

$\tau_c(t_b), \dot{\tau}_c(t_b)$, are parameters transmitted in CDMA signals within string of Types 10, 11 and 12 as shown in Table B-26 and Table B-27; and

10 800 seconds is the continuous time shift caused by the difference between Moscow time and Greenwich time.

3.1.2.2.3 Satellite position

3.1.2.2.3.1 The current satellite centre of mass position shall be defined using ephemeris parameters from GLONASS navigation, as indicated in Table B-17 for GLONASS FDMA signals, in Table B-20A for L1OC and in Table B-20B for L3OC.

3.1.2.2.3.2 Recalculation of ephemeris from instant t_b to instant t_i within the interval ($|\tau_i| = |t_i - t_b| \leq 15$ minutes) is performed using a technique of numeric integration of differential equations describing the motion of the satellites. In the right-hand parts of these equations the accelerations are determined using the gravitational constant μ and the second zonal harmonic of the geopotential J_2^0 which defines polar flattening of the earth, and accelerations due to luni-solar perturbation are taken into account. The equations are integrated in the PZ-90 (3.2.5) coordinate system by applying the Runge-Kutta technique of fourth order, as indicated below:

$$\frac{dx}{dt} = V_x$$

$$\frac{dy}{dt} = V_y$$

$$\frac{dz}{dt} = V_z$$

$$\frac{dV_x}{dt} = -\frac{\mu}{r^3}x - \frac{3}{2}J_2^0 \frac{\mu a_e^2}{r^5}x \left(1 - \frac{5z^2}{r^2}\right) + \omega^2x + 2\omega V_y + \ddot{x}$$

$$\frac{dV_y}{dt} = -\frac{\mu}{r^3}y - \frac{3}{2}J_2^0 \frac{\mu a_e^2}{r^5}y \left(1 - \frac{5z^2}{r^2}\right) + \omega^2y - 2\omega V_x + \ddot{y}$$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 47

$$\frac{dV_z}{dt} = -\frac{\mu}{r^3}z - \frac{3}{2}J_0^2 \frac{\mu a_e^2}{r^5}z \left(3 - \frac{5z^2}{r^2}\right) + \ddot{z}$$

where

- $r = \sqrt{x^2 + y^2 + z^2}$;
- $\mu =$ earth's universal gravitational constant ($398\,600.4418 \times 10^9 \text{ m}^3/\text{s}^2$);
- $a_e =$ major semi-axis (6 378 136 m);
- $J_0^2 =$ second zonal harmonic of the geopotential ($1\,082\,625.75 \times 10^{-9}$); and
- $\omega =$ earth's rotation rate ($7.2921151467 \times 10^{-5}$ radians/s).

Coordinates $x_n(t_b)$, $y_n(t_b)$, $z_n(t_b)$, and velocity vector components $\dot{x}_n(t_b) = V_x$, $\dot{y}_n(t_b) = V_y$, $\dot{z}_n(t_b) = V_z$ are initial conditions for the integration. Accelerations due to luni-solar perturbation $\ddot{x}_n(t_b)$, $\ddot{y}_n(t_b)$, $\ddot{z}_n(t_b)$ are constant on the integration interval ± 15 minutes.

3.1.2.2.3.3 Recalculation of ephemeris from instant t_b to instant t_i within the interval ($|t_i| = |t_i - t_b| \leq 4$ hours) for CDMA signals shall be performed as in 3.1.2.2.3.2, except that this model includes additional accelerations modelled by a fourth-degree polynomial to accommodate the extended interval as described below:

$$\frac{dx}{dt} = V_x$$

$$\frac{dy}{dt} = V_y$$

$$\frac{dz}{dt} = V_z$$

$$\frac{dV_x}{dt} = -\frac{\mu}{r^3}x - \frac{3}{2}J_0^2 \frac{\mu a_e^2}{r^5}x \left(1 - \frac{5z^2}{r^2}\right) + \omega^2x + 2\omega V_y + \ddot{x} + a_x$$

$$\frac{dV_y}{dt} = -\frac{\mu}{r^3}y - \frac{3}{2}J_0^2 \frac{\mu a_e^2}{r^5}y \left(1 - \frac{5z^2}{r^2}\right) + \omega^2y - 2\omega V_x + \ddot{y} + a_y$$

$$\frac{dV_z}{dt} = -\frac{\mu}{r^3}z - \frac{3}{2}J_0^2 \frac{\mu a_e^2}{r^5}z \left(3 - \frac{5z^2}{r^2}\right) + \ddot{z} + a_z$$

$$a_x = \Delta a_{x0} + a_{x1}(t - t_b) + a_{x2}(t - t_b)^2 + a_{x3}(t - t_b)^3 + a_{x4}(t - t_b)^4$$

$$a_y = \Delta a_{y0} + a_{y1}(t - t_b) + a_{y2}(t - t_b)^2 + a_{y3}(t - t_b)^3 + a_{y4}(t - t_b)^4$$

$$a_z = \Delta a_{z0} + a_{z1}(t - t_b) + a_{z2}(t - t_b)^2 + a_{z3}(t - t_b)^3 + a_{z4}(t - t_b)^4$$

Coordinates, velocity vector components at the time t_b , and perturbing accelerations $\ddot{x}, \ddot{y}, \ddot{z}$ shall be transmitted in CDMA signals within string of Types 10, 11 and 12. The long-term dynamic model parameters for the fourth-degree polynomials, accelerations a_x, a_y , and a_z , shall be transmitted in CDMA signals in strings of Types 31 and 32.

3.1.2.2.4 Algorithm for determination of satellite antenna phase centre position

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 48

3.1.2.2.4.1 For high-precision pseudo-range measurements, an algorithm for computing antenna phase centre position in the PZ-90 coordinate system based on the satellite centre of mass position and data transmitted in CDMA signals within string Type 16 shall be used.

Note. — Additional information concerning a suitable algorithm is given in Appendix R of the GLONASS CDMA ICD General Description.

3.1.2.2.5 Ionospheric Correction

3.1.2.2.5.1 The ionospheric correction for a single-frequency receiver shall be defined as:

- for pseudo-ranges, m: $\Delta S_{ion} = 0.40364 \cdot \frac{I_e}{f^2}$;
- for velocities, m/s: $\Delta V_{ion} = 0.40364 \cdot \frac{\dot{I}_e}{f^2}$,

where

f is the signal carrier frequency, in GHz;

I_e is the total electron content (TEC) integrated along the signal propagation path, $1 \times 10^{16} \text{m}^{-2}$; and

\dot{I}_e is the rate of change of TEC integrated along the signal propagation path, $1 \times 10^{16} \text{m}^{-2} \text{s}^{-1}$.

Note. — Additional information concerning two suitable algorithms for computing TEC integrated along the signal propagation path based on data transmitted within strings of Type 25 is given in Appendix Q of the GLONASS CDMA ICD General Description. The first algorithm is a universal algorithm for terrestrial and space users. It is more complex, accurate, and has wider application. The second algorithm is intended for terrestrial users only. It is easier to implement but it results in larger errors of TEC at less than 30° elevation angles. Residual ionosphere correction errors of the second algorithm do not exceed 4 m (0.95 probability).

3.1.2.3 Aircraft Elements

3.1.2.3.1 GLONASS Receiver

3.1.2.3.1.1 Reserved

3.1.2.3.1.2 Satellite tracking. The receiver shall provide the capability to continuously track a minimum of four satellites and generate a position solution based upon those measurements.

3.1.2.3.1.3 Doppler shift. The receiver shall be able to compensate for dynamic Doppler shift effects on nominal GLONASS signal carrier phase and standard code measurements. The receiver shall compensate for the Doppler shift that is unique to the anticipated application.

3.1.2.3.1.4 Resistance to interference. The receiver shall meet the requirements for resistance to interference as specified in 3.7.

3.1.2.3.1.4.1 Intrasystem interference. When receiving an FDMA navigation signal with frequency channel $k = n$, the interference created by a navigation signal with frequency channel number $k = n - 1$ or $k = n + 1$ shall not be more than -48 dBc with respect to the minimum specified satellite power at the surface of the earth provided that the satellites transmitting these signals are simultaneously located in user's visibility zone.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 49

Note. — The intrasystem interference is the intercorrelation properties of the ranging pseudo-random signal with regard to frequency division multiple access.

3.1.2.3.1.4.2 For CDMA signals, multiple access interference shall be defined by the intercorrelation properties of ranging codes and will depend on the number of elementary symbols N in the periods of these codes. Multiple access interference power in relation to the power of the L1OCd signal shall not exceed the level of -30 dB. Multiple access interference power in relation to the power of the L1OCp signal shall not exceed the level of -36 dB. Multiple access interference power in relation to the power of the L3OC signal shall not exceed the level of -40 dB.

3.1.2.3.1.5 Application of clock and ephemeris data. The receiver shall ensure that it is using the correct ephemeris and clock data before providing any position solution.

3.1.2.3.1.6 Leap second correction. Upon GLONASS time leap second correction (see 3.2.1.3.1, t_b) the GLONASS receiver shall be capable of:

- a) generating a smooth and valid series of pseudo-range measurements; and
- b) resynchronizing the data string time mark without loss of signal tracking.

3.1.2.3.1.6.1 After GLONASS time leap second correction the GLONASS receiver shall utilize the UTC time as follows:

- a) utilize the old (prior to the correction) UTC time together with the old ephemeris (transmitted before 00 hours 00 minutes 00 seconds UTC); and
- b) utilize the updated UTC time together with the new ephemeris (transmitted after 00 hours 00 minutes 00 seconds UTC).

Note — Additional information concerning the specific aspects of receiver operation during scheduled corrections of GLONASS time and Moscow time in the specified situations is given in Appendix E of the GLONASS CDMA ICD General Description.

3.1.2.4 Time

3.1.2.4.1 For the GLONASS-M satellites, the navigation message shall contain the data necessary to relate UTC(SU) time to UT1. GLONASS time shall be maintained to be within 1 millisecond of UTC(SU) time after correction for the integer number of hours due to GLONASS control segment specific features:

$$| t_{\text{GLONASS}} - (\text{UTC} + 03 \text{ hours } 00 \text{ minutes}) | < 1 \text{ ms}$$

The navigation data shall contain the requisite data to relate GLONASS time to UTC time (as maintained by the National Time Service of Russia, UTC (SU)) within 1 microsecond.

Note 1- The timescales of GLONASS satellites are periodically compared with central synchronizer time. Corrections to the timescales of GLONASS satellites relative to GLONASS time and UTC(SU) time are computed at the GLONASS ground-based control complex and uploaded to the satellites twice per day.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 50

Note 2 - There is no integer-second difference between GLONASS time and UTC time. The GLONASS timescale is periodically corrected to integer number of seconds simultaneously with UTC corrections which are performed according to the Bureau International de l'Heure notification (leap second correction). These corrections are performed at 00 hours 00 minutes 00 seconds UTC time at midnight at the end of a quarter of the year. Upon the GLONASS leap second correction the time mark within navigation message changes its position (in a continuous timescale) to become synchronized with 2-second epochs of corrected UTC timescale. GLONASS users are notified in advance on these planned corrections. For the GLONASS-M satellites, notification of these corrections is provided to users via the navigation message parameter KP.

3.1.2.4.2 Accuracy of mutual satellite timescales synchronization shall be 20 nanoseconds (1 sigma) for GLONASS satellites and 8 nanoseconds (1 sigma) for GLONASS-M satellites.

3.1.2.4.3 The correction to GPS time relative to GLONASS time (or difference between these timescales) broadcast by the GLONASS-M satellites, τ_{GPS} , shall not exceed 30 nanoseconds (1 sigma).

Note - The accuracy of τ_{GPS} (30 ns) is determined with reference to the GPS SPS coarse acquisition signal and may be refined upon completion of trials of the GLONASS system using GLONASS-M satellites.

3.1.2.4.4 Signal time shall be generated and maintained by an on-board clock based on atomic frequency standard, shall be synchronized with GLONASS time and shall be distributed in radio navigation signals.

Note 1. — Signal time differs from on-board clock time by the group delay value. Thus signal time corrections in string Types 10, 11 and 12 include group delay values.

Note 2. — Additional information concerning signal time is given in the GLONASS CDMA ICD General Description.

3.1.2.4.4.1 Navigation data for any GLONASS CDMA signal shall contain the estimated parameters of the polynomial model for relating signal time broadcast in this signal to GLONASS time as well as for relating a pilot component of this signal to its data component.

3.1.2.4.4.2 When GLONASS time is corrected for ± 1 s during scheduled leap second corrections of UTC(SU), simultaneous correction of signal time for all satellites shall be carried out through changing the time stamps of the pulse sequence representing seconds.

Note. — Navigation data provides advance notifications to users of the day and the sign of the correction.

3.1.2.5 Coordinate System

3.1.2.5.1 PZ-90 (Parameters of common terrestrial ellipsoid and gravitational field of the earth 1990). The GLONASS broadcast ephemeris shall describe a position of transmitting antenna phase centre of a given satellite in the PZ-90 earth-centered earth-fixed reference frame.

3.1.2.5.2 Conversion Between PZ-90 and WGS-84

3.1.2.5.2.1 The following conversion parameters should be used to obtain position coordinates in WGS-84 (version G1674) from position coordinates in PZ-90 (Version PZ-90.11):

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 51

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix}_{WGS-84} = \begin{bmatrix} 1 & -0.0097 \times 10^{-9} & -0.0097 \times 10^{-9} \\ -0.0097 \times 10^{-9} & 1 & -0.2036 \times 10^{-9} \\ -0.2036 \times 10^{-9} & -0.0097 \times 10^{-9} & 1 \end{bmatrix} \times \begin{bmatrix} x \\ y \\ z \end{bmatrix}_{PZ-90} + \begin{bmatrix} 0.003 \\ 0.001 \\ 0 \end{bmatrix}$$

Note 1 - X, Y and Z are expressed in meters. The difference between versions WGS-84 (G1674) and PZ-90 (PZ-90.11) is not significant with respect to operational requirements.

Note 2 - Guidance material on conversion between PZ-90 and WGS-84 is provided in Attachment D, section 4.1.2.9.3.

3.1.3 Galileo Open Service (Galileo OS)

3.1.3.1. Non-Aircraft elements

3.1.3.1.1 Galileo RF Characteristics

3.1.3.1.1.1 E1 and E5 common requirements

3.1.3.1.1.1.1 *Carrier phase noise.* The carrier phase noise spectral density of the unmodulated carrier on E5 and E1 shall be such that a second-order phase locked loop of 10 Hz one-sided noise bandwidth is able to track the carrier to an accuracy of 0.04 radian root mean square (RMS).

3.1.3.1.1.1.2 *Spurious emissions.* In-band spurious emissions shall be at least 35 dB below the unmodulated E1 and E5 carriers over the allocated channel bandwidth.

3.1.3.1.1.1.3 *Correlation loss.* The loss in the recovered signal power due to imperfections in the signal modulation and waveform distortion shall not exceed 0.6 dB for each signal (E1, E5a and E5b).

Note. — The loss in signal power is the difference between the broadcast power in the specified bandwidth and the signal power recovered by a noise-free, loss-free receiver with 1-chip correlator spacing and the same bandwidth.

3.1.3.1.1.1.4 *Code/data coherence.* The edge of each data symbol shall be aligned with the edge of the corresponding ranging code chip. The start of the periodic ranging code shall be aligned with the start of a data symbol. The edge of each secondary code chip shall be aligned with the edge of a primary code chip. The start of a primary code chip shall be aligned with the start of a secondary code chip.

3.1.3.1.1.2 E1 RF characteristics

3.1.3.1.1.2.1 *E1 signal components.* The E1 signal shall comprise two signal components: E1-B navigation data component with a navigation data symbol rate of 250 symbols per second and E1-C pilot component.

3.1.3.1.1.2.2 *E1 signal power split.* The E1 signal power shall be equally split between the E1-B and E1-C signal components.

3.1.3.1.1.2.3 *E1-B ranging code (C_{E1-B}).* The E1-B ranging code shall be a 1.023 megachips per second ranging code repeated every 4 milliseconds, derived from a primary ranging code of 4 092 chips.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 52

Note. — Additional information concerning the E1-B ranging codes is given in Galileo OS SIS ICD, Chapter 3 and Annex C.

3.1.3.1.1.2.4 *E1-C ranging code (C_{E1-C}).* The E1-C ranging code shall be a 1.023 megachips per second ranging code repeated every 100 milliseconds, derived from the Modulo-2 addition of a primary ranging code of 4 092 chips and a secondary code of 25 chips.

Note. — Additional information concerning the E1-C ranging codes is given in Galileo OS SIS ICD, Chapter 3 and Annex C.

3.1.3.1.1.2.5 *E1-B data component generation.* The E1-B data component shall be generated from the E1 navigation data stream (D_{E1-B}) and the E1-B ranging code (C_{E1-B}), modulated with two in-phase CBOC subcarriers of 1.023 MHz and 6.138 MHz, respectively, as shown in Figure GAL-1.

Note. — The subcarrier-free component of the E1 navigation data component — that is, before CBOC modulation — is denoted as e_{E1-B} . Additional information concerning e_{E1-B} generation is given in Galileo OS SIS ICD, 2.3.3.

3.1.3.1.1.2.6 *E1-C pilot component generation.* The E1-C pilot component shall be generated from the E1-C ranging code (C_{E1-C}) modulated with two anti-phase CBOC subcarriers of 1.023 MHz and 6.138 MHz, respectively, as shown in Figure GAL-1.

Note. — The subcarrier-free component of the E1 pilot component — that is, before CBOC modulation — is denoted as e_{E1-C} . Additional information concerning e_{E1-C} generation is given in Galileo OS SIS ICD, 2.3.3.

3.1.3.1.1.2.7 *E1 signal modulation.* The E1-B/C composite binary signal shall be generated from the CBOC modulation of the binary signal components, e_{E1-B} and e_{E1-C} , and the subcarriers, as illustrated in Figure B-13.

Note. — Additional information concerning E1-B/C generation is given in Galileo OS SIS ICD, 2.3.3.

3.1.3.1.1.3 E5a and E5b RF characteristics

3.1.3.1.1.3.1 *E5a signal components.* The E5a signal shall comprise two signal components: E5a-I navigation data component with a navigation data symbol rate of 50 symbols per second and E5a-Q pilot component.

3.1.3.1.1.3.2 *E5a signal power split.* The E5a signal power shall be equally split between the E5a-I and E5a-Q components.

3.1.3.1.1.3.3 *E5a-I ranging code (C_{E5a-I}).* The E5a-I ranging code sequence shall be a 10.230 megachips per second ranging code repeated every 20 milliseconds, derived from the Modulo-2 addition of a primary ranging code of 10 230 chips and a secondary code of 20 chips.

Note. — Additional information concerning E5a-I ranging codes is given in Galileo OS SIS ICD, Chapter 3 and Annex C.

3.1.3.1.1.3.4 *E5a-Q ranging code (C_{E5a-Q}).* The E5a-Q ranging code shall be a 10.230 megachips per second ranging code repeated every 100 milliseconds, derived from the Modulo-2 addition of a primary ranging code of 10 230 chips and a secondary code of 100 chips.

	Aeronautical telecommunication Volume - I		BCAR-10	
	Technical provision for GNSS		Appendix-B	Page: 53

Note. — Additional information concerning E5a-Q ranging codes is given in Galileo OS SIS ICD, Chapter 3 and Annex C.

3.1.3.1.1.3.5 *E5a-I data component generation.* The E5a data component shall be generated from the E5a navigation data stream (D_{E5a-I}) and the E5a-I ranging code (C_{E5a-I}).

Note. — The subcarrier-free component of the E5a navigation data component — that is, before AltBOC modulation — is denoted as e_{E5a-I} .

3.1.3.1.1.3.6 *E5a-Q pilot component generation.* The E5a pilot component shall be generated from the E5a-Q ranging code (C_{E5a-Q}).

Note. — The subcarrier-free component of the E5a pilot component — that is, before AltBOC modulation — is denoted as e_{E5a-Q} .

3.1.3.1.1.3.7 *E5b signal components.* The E5b signal shall comprise two signal components: E5b-I navigation data component with a navigation data symbol rate of 250 symbols per second and E5b-Q pilot component.

3.1.3.1.1.3.8 *E5b signal power split.* The E5b signal power shall be equally split between the E5b-I and E5b-Q components.

3.1.3.1.1.3.9 *E5b-I ranging code (C_{E5b-I}).* The E5b-I ranging code shall be a 10.230 megachips per second ranging code repeated every 4 milliseconds, derived from the Modulo-2 addition of a primary ranging code of 10 230 chips and a secondary code of 4 chips.

Note. — Additional information concerning E5b-I ranging codes is given in Galileo OS SIS ICD, Chapter 3 and Annex C.

3.1.3.1.1.3.10 *E5b-Q Ranging code (C_{E5b-Q}).* The E5b-Q ranging code shall be a 10.230 megachips per second ranging code repeated every 100 milliseconds, derived from the Modulo-2 addition of a primary ranging code of 10 230 chips and a secondary code of 100 chips.

Note. — Additional information concerning E5b-Q ranging codes is given in Galileo OS SIS ICD, Chapter 3 and Annex C.

3.1.3.1.1.3.11 *E5b-I data component generation.* The E5b data component shall be generated from the E5b navigation data stream (D_{E5b-I}) and the ranging code (C_{E5b-I}).

Note. — The subcarrier-free component of the E5b navigation data component — that is, before AltBOC modulation — is denoted as e_{E5b-I} .

3.1.3.1.1.3.12 *E5b-Q pilot component generation.* The E5b pilot component shall be generated from the ranging code (C_{E5b-Q}).

Note. — The subcarrier-free component of the E5b pilot component — that is, before AltBOC modulation — is denoted as e_{E5b-Q} .

3.1.3.1.1.3.13 *E5 signal modulation.* The wideband E5 signal shall be generated with the AltBOC modulation of side-band subcarrier of 15.345 MHz (15×1.023 MHz) with the binary signal components e_{E5a-I} , e_{E5a-Q} , e_{E5b-I} and e_{E5b-Q} , as illustrated in Figure B-14.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

Note 1.— E5a and E5b signals can be processed independently by the user receiver as though they were two separate QPSK signals with a carrier frequency of 1176.45 MHz and 1207.14 MHz, respectively.

Note 2.— Additional information concerning E5 generation is given in Galileo OS SIS ICD, 2.3.1.

3.1.3.1.1.4 Code assignments to satellites

3.1.3.1.1.4.1 *Primary ranging code assignment to satellites.* The E5a-I, E5a-Q, E1-B and E1-C primary code number n shall be allocated to the space vehicle IDs (SVID) number n (with n=1 to 36).

3.1.3.1.1.4.2 *Secondary ranging code assignment to satellites.* The E5a-Q secondary code shall be assigned according to the SVID number n (with n=1 to 36). E5a-I and E1-C secondary codes shall be constant regardless of the SVID.

3.1.3.1.2 DATA STRUCTURE

Note. — Additional information concerning the data structure is given in Galileo OS SIS ICD.

3.1.3.1.2.1 E5a-I message (F/NAV) characteristics

3.1.3.1.2.1.1 The E5a-I message shall be transmitted as a sequence of frames as indicated in Figure B-15. The period of each frame shall be 600 seconds. Each frame shall consist of 12 subframes of period 50 seconds per subframe. Each subframe shall consist of five pages of period 10 seconds per page.

3.1.3.1.2.1.2 *Page structure.* Each page structure shall contain the following elements structured as indicated in Table B-30:

- 12 synchronization block symbols
- 488 interleaved message block symbols

Table B-30. F/NAV page layout

<i>Sync.</i>	<i>F/NAV symbols</i>			<i>Total (symbols)</i>
12	488			500
<i>F/NAV word (bits)</i>		<i>Tail (bits)</i>		<i>Total (bits)</i>
Page type	Nav. data	CRC	6	244
6	208	24		

3.1.3.1.2.1.3 *Synchronization block.* The first element of each page shall be a 12-symbol synchronization sequence. The synchronization sequence shall be “101101110000” with the MSB transmitted first, and it shall be added to the beginning of the 488 interleaved message block symbols field after the interleaving procedure described in paragraph 3.1.3.1.2.1.6.

3.1.3.1.2.1.4 *F/NAV message word.* The message word shall contain 244 bits consisting of a 6-bit page type, a 208-bit data field, a 24-bit CRC and a 6-bit tail field. The 6-bit tail field shall be “000000”.

Note.— Additional information concerning the message words is given in Galileo OS SIS ICD.

3.1.3.1.2.1.5 *F/NAV FEC encoding.* The 25-bit-per-second data stream shall be encoded at a rate of two symbols per bit using a convolution code with a constraint length of seven to yield 50 symbols per second. The convolution encoder logic arrangement shall be as illustrated in Figure B-16 with the G1 output selected for the first half of each 40-millisecond data bit period resulting in 488 symbols per page where S₁ is the first symbol and S₄₈₈ is the last symbol.

3.1.3.1.2.1.6 *E5a-I interleaving procedure.* The E5a-I message block symbols shall be interleaved using a 61-column, 8-row matrix, where each entry is one symbol. The message block symbols shall be written into each column and ordered for transmission, row by row, starting at the upper left corner of the matrix as indicated in Table B-31

Table B-31. E5a-I interleaver matrix

Columns→ Rows ↓	C ₁	C ₂	C ₃	...	C ₆₀	C ₆₁
R ₁	S ₁	S ₉	S ₁₇	...	S ₄₇₃	S ₄₈₁
R ₂	S ₂	S ₁₀	S ₁₈	...	S ₄₇₄	S ₄₈₂
R ₃	S ₃	S ₁₁	S ₁₉	...	S ₄₇₅	S ₄₈₃
...
R ₇	S ₇	S ₁₅	S ₂₃	...	S ₄₇₉	S ₄₈₇
R ₈	S ₈	S ₁₆	S ₂₄	...	S ₄₈₀	S ₄₈₈

3.1.3.1.2.2 E1-B message (I/NAV) characteristics

3.1.3.1.2.2.1 The E1-B message shall be transmitted as a sequence of frames as indicated in Figure B-17. The period of each frame shall be 720 seconds. Each frame shall consist of 24 subframes of period 30 seconds per subframe. Each subframe consist of 15 nominal pages of period 2 seconds per page. Each page shall consist of two subpages each of period one second.

Note 1.— The two subpages in a page are known as the even page and the odd page.

Note 2.— I/NAV message structure is indicated in Figure B-17.

3.1.3.1.2.2.2 *Page type.* There shall be two types of pages, a nominal page and an alert page. The nominal page shall contain the nominal data word.

Note.— The alert page is reserved for future applications.

3.1.3.1.2.2.3 *Nominal page.* A nominal page shall consist of two parts (even and odd) transmitted sequentially over the same frequency and structured as indicated in Table B-33. The nominal page shall contain 240 bits so that the first 120 bits shall be in the even nominal subpage, and the second 120 bits shall be in the odd nominal subpage.

3.1.3.1.2.2.4 *Nominal data word.* The nominal E1-B data word shall contain 128 bits consisting of a 6-bit word type and a 122-bit data field.

3.1.3.1.2.2.5 *Subpage structure.* Each subpage structure shall contain the following elements, structured as indicated in Table B-32:

- a) 10 synchronization block symbols; and
- b) 240 interleaved message block symbols.

Table B-32. I/NAV subpage layout

<i>Sync.</i>	<i>I/NAV subpage (even or odd) symbols</i>	<i>Total (symbols)</i>
10	240	250

<i>I/NAV subpage (even or odd) bits</i>	<i>Tail (bits)</i>	<i>Total (bits)</i>
114	6	120

3.1.3.1.2.2.6 *Synchronization block.* The first element of each subpage shall be a 10-symbol synchronization sequence. The synchronization sequence shall be “0101100000”, with the MSB transmitted first, and shall be added to the beginning of the 240 interleaved message block symbols field after the interleaving procedure described in paragraph 3.1.3.1.2.2.10.

3.1.3.1.2.2.7 *Even subpage.* The even subpage shall contain a bit denoting which part (even or odd) of the subpage is being transmitted, a type bit to indicate that this is a nominal page, the first 112 bits of the nominal data word and a 6-bit tail field, as indicated in Table B-33. The tail field shall be “000000”.

3.1.3.1.2.2.8 *Odd subpage.* The odd subpage shall contain a bit denoting which part (even or odd) of the subpage is being transmitted, a type bit to indicate that this is a nominal page, the last 16 bits of the nominal data word, a 40-bit “reserved 1” field, 22 bits for search and rescue (SAR) data, a 2-bit spare field, a 24-bit CRC, an 8-bit “reserved 2” field and a 6-bit tail field, as indicated in Table B-33. The tail field shall be “000000”.

Note.— Galileo provides enhanced distress localization and call features for the provision of a SAR service interoperable with the COSPAS-SARSAT system. Galileo SAR service is out of the scope of Annex 10.

Table B-33. I/NAV nominal page with bits allocation

<i>E1-B</i>									
<i>Even/odd=1</i>	<i>Page Type=0</i>	<i>Data word (2/2)</i>	<i>Reserved 1</i>	<i>SAR</i>	<i>Spare</i>	<i>CRC</i>	<i>Reserved 2</i>	<i>Tail</i>	<i>Total (bits)</i>
1	1	16	40	22	2	24	8	6	120
<i>Even/odd=0</i>	<i>Page Type=0</i>	<i>Data word (1/2)</i>						<i>Tail</i>	<i>Total (bits)</i>
1	1	112						6	120

Note 1.— Even/odd field (1 bit) indicates the part of the page (0=even/1=odd) that is broadcast.

Note 2.— Page type field (1 bit) equal to 0 indicates the nominal page type.

Note 3.— Data field consists of a nominal data word (described in 3.1.3.1.2.2.4) of 128 bits (comprising 112 bits of data (1/2) and 16 bits of data (2/2)).

3.1.3.1.2.2.9 I/NAV FEC encoding. The 125-bit-per-second data in the even and odd subpages shall be encoded at a rate of two symbols per bit using a convolutional code with a constraint length of seven to yield 250 symbols per second. The convolutional encoder logic arrangement shall be as illustrated in Figure B-18 with the G1 output selected for the first half of each 8-millisecond data bit period resulting in 240 symbols per page, where S_1 is the first symbol and S_{240} is the last symbol.

3.1.3.1.2.2.10 E1-B interleaving procedure. The E1-B message block symbols shall be interleaved using a 30 column by an eight-row matrix, where each entry is one symbol. The message block symbols shall be written into each column and ordered for transmission row by row starting at the upper left corner of the matrix, as indicated in Table B-34.

Table B-34. E1-B interleaver matrix

Columns→ Rows ↓	C ₁	C ₂	C ₃	...	C ₂₉	C ₃₀
R ₁	S ₁	S ₉	S ₁₇	...	S ₂₂₅	S ₂₃₃
R ₂	S ₂	S ₁₀	S ₁₈	...	S ₂₂₆	S ₂₃₄
R ₃	S ₃	S ₁₁	S ₁₉	...	S ₂₂₇	S ₂₃₅
...
R ₇	S ₇	S ₁₅	S ₂₃	...	S ₂₃₁	S ₂₃₉
R ₈	S ₈	S ₁₆	S ₂₄	...	S ₂₃₂	S ₂₄₀

3.1.3.1.2.2.11 *Transmission sequence of nominal pages on E1.* The pages shall be transmitted on E1-B such that the even subpage of any word shall be transmitted before the odd subpage of the same word.

3.1.3.1.3 Data content

Note.— Additional information concerning Galileo OS navigation data content and parameters is given in Galileo OS SIS ICD, Chapters 4 and 5.

3.1.3.1.3.1 The contents of F/NAV E5a-I page types shall be according to Table B-35.

Note 1.— The odd numbered subframes contain page type 5 and the even numbered subframes contain page type 6. This allows transmission of the almanacs for three satellites within two successive subframes (100 seconds).

Note 2.— The parameter *k* is a designator for “satellite number 1”, *k*+1 is a designator for “satellite number 2”, etc. It is not a navigation data parameter. *k* is set by the Galileo control system. The complete F/NAV frame layout (12 subframes) can transmit the almanacs for 18 satellites, sequenced as indicated in Galileo OS SIS ICD, 4.2.3.

Note 3.— Additional information concerning the bit allocation of the different F/NAV page types is given in Galileo OS SIS ICD, 4.2.4.

Table B-35. F/NAV E5a-I page types content

<i>Page type</i>		<i>Page content</i>
Odd subframe	1	IODnav, SVID, clock correction, SIS accuracy index (SISA), ionospheric correction, broadcast group delay (BGD), signal health status (SHS), Galileo system time (GST) and data validity status (DVS)
	2	IODnav, ephemeris (1/3) and GST
	3	IODnav, ephemeris (2/3) and GST
	4	IODnav, ephemeris (3/3), GST-UTC conversion, GST-GPS conversion and time-of-week (TOW)
	5	IODa, almanac week number, almanac reference time, almanac for satellite $k+3(n-1)/2$ and almanac for satellite $(k+1)+3(n-1)/2$ part 1; where n is the number of the subframe
Even subframe	1	IODnav, SVID, clock correction, SISA, ionospheric correction, BGD, SHS, GST and DVS
	2	IODnav, ephemeris (1/3) and GST
	3	IODnav, ephemeris (2/3) and GST
	4	IODnav, ephemeris (3/3), GST-UTC conversion, GST-GPS conversion and TOW
	6	IODa, almanac for satellite $(k+1)+3(n-2)/2$ part 2 and almanac for satellite $(k+2)+3(n-2)/2$; where n is the number of the subframe

3.1.3.1.3.2 The contents of I/NAV E1-B word types shall be according to Table B-36.

Note 1.— Additional information concerning I/NAV nominal subframe layout is given in Galileo OS SIS ICD, 4.3.3.

Note 2.— The parameter k changes every two subframes (i.e. subframes 1 and 2 have the same k, subframes 3 and 4 have the next, etc.). The complete I/NAV frame layout (24 subframes) can transmit the almanacs for 36 satellites, sequenced as indicated in Galileo OS SIS ICD, 4.3.4.

Note 3.— Additional information concerning the bit allocations of the different I/NAV word types is given in Galileo OS SIS ICD, 4.3.5.

Table B-36. I/NAV E1-B word types content

<i>Word type</i>	<i>Word content</i>
0	Spare word
1	IODnav and ephemeris (1/4)
2	IODnav and ephemeris (2/4)
3	IODnav and ephemeris (3/4)
4	IODnav, SVID, ephemeris (4/4) and clock correction
5	Ionospheric correction, BGD, SHS, GST and DVS
6	GST-UTC conversion and TOW
7	IODa, almanac for satellite k (part 1), almanac reference time and almanac reference week number
8	IODa, almanac for satellite k (part 2) and satellite k+1 (part 1)
9	IODa, almanac reference time, almanac reference week number, almanac for satellite k+1 (part 2) and satellite k+2 (part 1)
10	IODa, almanac for satellite k+2 (part 2) and GST-GPS conversion parameters

3.1.3.1.3.3 Ephemeris parameters shall be provided in both I/NAV and F/NAV messages transmitted by each Galileo satellite. A single ephemeris shall be applicable to all signals of a specific satellite.

Note.— The ephemeris is computed with respect to the antenna apparent phase centre common to every frequency.

3.1.3.1.3.4 The Galileo OS SIS status shall take one of the following three values:

- SIS “healthy”: the SIS is expected to meet the minimum performance requirements.
- SIS “unhealthy”: the SIS is out of service or under test.
- SIS “marginal”: the SIS is in neither of the two previous states.

3.1.3.1.3.4.1 The status of the SIS shall be encoded within the navigation message through three SIS status flags: the signal health status (SHS) flag, the data validity status (DVS) flag and the SIS accuracy index (SISA).

Note.— Additional information concerning the position of the Galileo SIS status flags within the navigation message is given in Galileo OS SIS ICD, 5.1.9.3 and 5.1.12.

3.1.3.1.3.4.2 *SISA*. The *SISA* shall be encoded as shown in Table B-37.

Table B-37. SISA index

<i>SISA</i>	<i>SIS accuracy value (m)</i>
0 to 49	0 m to 0.49 m with 1 cm resolution
50 to 74	0.50 m to 0.98 m with 2 cm resolution
75 to 99	1.00 m to 1.96 m with 4 cm resolution
100 to 125	2.00 m to 6.00 m with 16 cm resolution
126 to 254	Spare
255	No Accuracy Prediction Available (NAPA)

3.1.3.1.3.4.3 SISA shall be coded as shown in Table B-38.

Table B-38. SISA parameters

<i>Parameter</i>	<i>Definition</i>	<i>BITS</i>	<i>Scale factor</i>	<i>Units</i>
SISA (E1, E5a)	SIS accuracy index for dual-frequency E1-E5a	8	N/A	Dimensionless
SISA (E1, E5b)	SIS accuracy index for dual-frequency E1-E5b	8	N/A	Dimensionless

3.1.3.1.3.4.4 *Signal health status (SHS)*. The SHS index shall be encoded according to the values stated in Table B-39.

Table B-39. Signal health status index

<i>SHS index</i>	<i>Signal status definition</i>
0	Signal OK
1	Signal out of service
2	Signal will be out of service
3	Signal in test mode

3.1.3.1.3.4.5 *Data validity status (DVS)*. The DVS index shall be encoded according to the values in Table B-40.

Table B-40. Data validity status index

<i>Data validity status index</i>	<i>Signal status definition</i>
0	Navigation data valid (NDV)
1	Working without guarantee (WWG)

3.1.3.1.3.4.6 The mapping between the values of the SIS status flags shall be as presented in Table B-41.

Table B-41. Galileo OS SIS status vs SIS status flags

<i>SIS status</i>	<i>Dummy message</i>	<i>SIS flags</i>		
		<i>SHS</i>	<i>DVS</i>	<i>SISA</i>
Healthy	NO	Ok	NDV	Not NAPA
Unhealthy	NO	Out of service	Any value	Any value
	NO	In test	Any value	Any value
	YES	N/A	N/A	N/A
Marginal	NO	Ok	WWG	Any value
	NO	Ok	Any value	NAPA
	NO	Will be out of service	Any value	Any value

Note.— Additional information concerning Galileo flags is given in the European GNSS (Galileo) Open Service Definition Document (Issue 1.1), dated May 2019 (hereinafter referred to as “Galileo OS SDD”).

3.1.3.1.3.5 *Almanac.* F/NAV and I/NAV messages shall contain the almanac data for a constellation of up to 36 satellites. The almanac data shall be a reduced-precision subset of the clock and ephemeris parameters of the active Galileo satellites in orbit. Also, a predicted satellite health status shall be provided for each of these satellites, giving indications on the satellite’s signal components health and navigation data health.

3.1.3.1.3.6 *Dummy messages.* If no valid F/NAV or I/NAV data can be transmitted, then the satellite shall transmit a dummy page with a message ID of 63 in the respective F/NAV or I/NAV signals.

Note.— Additional information concerning the dummy page is given in Galileo OS SIS ICD, 4.2.5 and 4.3.6.

3.1.3.1.3.7 *Issue of data (IOD).* The Galileo satellite shall broadcast the navigation parameters in data sets. Every set of navigation data broadcast by a Galileo satellite shall be identified by an IOD value.

Note.— Two independent IODs are defined for the ephemeris, satellite clock correction parameters and SISA (“IODnav”) and the almanacs (“IODa”).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 63

3.1.3.1.3.7.1 The IODnav value broadcast by a Galileo satellite in a set of navigation data (ephemeris and clock corrections) shall be unique with respect to any other IODnav broadcast by the same Galileo satellite in the previous 240 minutes.

3.1.3.1.3.8 *Navigation data validity time.* In nominal operations, each navigation message data set shall be superseded before its expiration at four hours by the broadcast of a new navigation message data set.

Note.— The nominal period of ephemeris and clock corrections update ranges from 10 minutes to three hours.

3.1.3.1.3.9 *Galileo time of week (TOW).* The TOW shall cover an entire week from 0 to 604 799 seconds and shall be reset to zero at the end of each week.

Note.— The TOW is defined as the number of seconds that have occurred since the transition from the previous week.

3.1.3.1.3.10 *Galileo week number (WN).* The WN shall consist of 12 bits, which covers 4 096 weeks. The counter shall be reset to zero to cover an additional period Modulo 4 096.

Note.— The WN is an integer counter that gives the sequential week number from the GST start epoch.

3.1.3.2 DEFINITIONS OF PROTOCOLS FOR DATA APPLICATION

3.1.3.2.1 *Parity check algorithm.* For the F/NAV and the I/NAV data, a CRC of 24 bits shall be generated from the following generator polynomial $G(X)$:

$$G(X) = (1 + X)P(X)$$

where

$$P(X) = X^{23} + X^{17} + X^{13} + X^{12} + X^{11} + X^9 + X^8 + X^7 + X^5 + X^3 + 1$$

Note.— The CRC code is calculated in accordance with section 3.9 of this Appendix

3.1.3.2.1.1 The F/NAV CRC information field, $M(X)$, shall be computed using the equation:

$$M(X) = \sum_{i=1}^{214} m_i X^{214-i} = m_1 X^{213} + m_2 X^{212} + \dots + m_{213} X + m_{214}$$

$M(X)$ shall be formed from the 6-bit E5a-I page type identifier and the 208-bit data field. Bits shall be arranged in the order transmitted from the Galileo satellite, such that m_1 corresponds to the first transmitted bit of the page type identifier, and m_{214} corresponds to bit 208 of the data field.

3.1.3.2.1.2 The I/NAV nominal page CRC information field, $M(X)$, shall be computed using the equation:

$$M(X) = \sum_{i=1}^{113} m_{e,i+1} X^{194-i} + \sum_{i=1}^{81} m_{o,i+1} X^{81-i} = m_{e,2} X^{193} + m_{e,3} X^{192} + \dots + m_{e,113} X^{82} + m_{e,114} X^{81} + m_{o,2} X^{80} + m_{o,3} X^{79} + \dots + m_{o,81} X + m_{o,82}$$

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 64

$M(x)$ shall be formed from the even (e)/odd (o) fields, page type fields, data word fields (1/2 and 2/2), reserved 1 field, SAR (on E1-B only) and spare fields. In nominal mode the CRC shall be computed for the even and odd subpages of the same frequency and shall always be broadcast in the odd subpage.

3.1.3.2.2 *Satellite clock correction parameters.* The predicted offset of the physical satellite signal time of transmission (TOT) relative to the satellite signal TOT in GST shall be computed for the dual-frequency signal combination using the following formula:

where

- $(X)=(f_1,f_2)$ is the dual-frequency combination f_1 and f_2 used for the clock model;
- $TOT_C(X)$ is the corrected satellite TOT in GST for the signal combination X;
- $TOT_m(X)$ is the physical satellite TOT for the signal combination X retrieved through pseudo-range measurements; and
- $\Delta t_{sv}(X)$ is the satellite time correction for the signal combination X computed by means of the time correction data retrieved from the navigation message, as follows:

$$\Delta t_{sv}(X)=a_{f0}(X)+a_{f1}(X)[t-t_{oc}(X)]+a_{f2}(X)[t-t_{oc}(X)]^2+\Delta t_r$$

where

- $a_{f0}(X)$, $a_{f1}(X)$, $a_{f2}(X)$ and $t_{oc}(X)$ are parameters transmitted in F/NAV signals page Type 1 and I/NAV signals word Type 4 as indicated in 3.1.3.1.3;
- $t_{oc}(X)$ is the reference time for the clock correction;
- t is the GST time in seconds; and
- Δt_r , expressed in seconds, is a relativistic correction term, given by $\Delta t_r=F e A^{1/2} \sin(E)$ where the orbital parameters (e , $A^{1/2}$) are transmitted in F/NAV signals page Type 2 and I/NAV signals word Type 1 as indicated in 3.1.3.1.3, E is the calculated eccentric anomaly and $F=-2\mu^{1/2}/c^2=-4.442807309 \times 10^{-10}$ s/m^{1/2}.

3.1.3.2.2.1 A single-frequency user receiver processing pseudo-ranges from the frequency f_i shall apply the following correction to the satellite clock correction Δt_{sv} defined in paragraph 3.1.3.2.2:

$$\Delta t_{sv}(f_1)=\Delta t_{sv}(f_1,f_2)-BGD(f_1,f_2)$$

where

$BGD(f_1,f_2)$ is the broadcast group delay transmitted in F/NAV signals page Type 1 and I/NAV signals word Type 5 as indicated in 3.1.3.1.3 and defined as follows:

$$BGD(f_1,f_2)=\frac{TR_1-TR_2}{1-\left(\frac{f_1}{f_2}\right)^2}$$

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 65

where

- f_1 and f_2 denote the carrier frequencies of E1 and E5a, respectively; and
- TR_1 and TR_2 are the group delays of the signals whose carrier frequencies are respectively f_1 and f_2 .

3.1.3.2.2.2 A single-frequency user receiver processing pseudo-ranges from the frequency f_2 shall apply the following correction to the satellite clock correction Δt_{SV} defined in paragraph 3.1.3.2.2:

$$\Delta t_{SV}(f_2) = \Delta t_{SV}(f_1, f_2) - \left(\frac{f_1}{f_2}\right)^2 BGD(f_1, f_2)$$

3.1.3.2.3 *GST-UTC conversion algorithm and parameters.* The UTC time t_{UTC} shall be computed through three different cases depending on the epoch of a possible leap second adjustment (scheduled future or recent past) given by the day number (DN), the day at the end of which the leap second becomes effective, and the week number (WN_{LSF}) to which DN is referenced. “Day one” of DN shall be the first day relative to the end/start of week and the WN_{LSF} value shall consist of eight bits, which are a Modulo 256 binary representation of the Galileo week number to which the DN is referenced. The following three cases shall apply:

Case A:

Whenever the leap second adjustment time indicated by WN_{LSF} and DN is not in the past (relative to the user’s present time), and the user’s present time does not fall in the time span which starts six hours prior to the effective time, and ends six hours after the effective time, t_{UTC} shall be computed as follows:

$$t_{UTC} = (t_E - \Delta t_{UTC})[\text{Modulo } 86400]$$

where

$$\Delta t_{UTC} = \Delta t_{LS} + A_0 + A_1(t_E - t_{0t} + 604800(WN - WN_{0t}))$$

Case B:

Whenever the user’s current time falls within the time span of six hours prior to the leap second adjustment time to six hours after the adjustment time, t_{UTC} shall be computed as follows (Δt_{UTC} as defined in Case A):

$$t_{UTC} = W[\text{Modulo } (86400 + \Delta t_{LSF} - \Delta t_{LS})]$$

where

$$W = (t_E - \Delta t_{UTC} - 43200)[\text{Modulo } 86400] + 43200$$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 66

Case C:

Whenever the leap second adjustment time is in the “past” (relative to the user’s current time), and the user’s present time does not fall in the time span which starts six hours prior to the leap second adjustment time, and ends six hours after the adjustment time, t_{UTC} shall be computed as follows:

$$t_{UTC} = (t_E - \Delta t_{UTC})[\text{Modulo } 86400]$$

where

$$\Delta t_{UTC} = \Delta t_{LSF} + A_0 + A_1(t_E - t_{0t} + 604800(WN - WN_{0t}))$$

- $A_0, A_1, \Delta t_{LS}, t_{0t}, WN_{0t}, WN_{LSF}, DN$ and Δt_{LSF} are GST to UTC time conversion parameters transmitted in F/NAV signals page Type 4 and I/NAV signals word Type 6 as indicated in 3.1.3.1.3;
- t_E is the GST as estimated by the user through its GST determination algorithm; and
- WN is the week number to which t_E is referenced.

3.1.3.2.4 *Satellite position.* The Earth-Centred, Earth-Fixed (ECEF) coordinates of the satellite antenna phase centre position at GST time t shall be computed using the following equations:

$$x = x' \cos(\Omega) - y' \cos(i) \sin(\Omega)$$

$$y = x' \sin(\Omega) + y' \cos(i) \cos(\Omega)$$

$$z = y' \sin(i)$$

where

$\Omega = \Omega_0 + (\dot{\Omega} - \omega_E)t_k - \omega_E t_{0e}$	corrected longitude of ascending node
$x' = r \cos u$	position in orbital plane
$y' = r \sin u$	position in orbital plane
$i = i_0 + \delta i + \frac{di}{dt} t_k$	corrected inclination
$r = A(1 - e \cos E) + \delta r$	corrected radius
$u = \Phi + \delta u$	corrected argument of latitude
$A = (A^{1/2})^2$	semi-major axis
$\delta r = C_{rs} \sin 2\Phi + C_{rc} \cos 2\Phi$	radius correction
$\delta u = C_{us} \sin 2\Phi + C_{uc} \cos 2\Phi$	argument of latitude correction
$\delta i = C_{is} \sin 2\Phi + C_{ic} \cos 2\Phi$	inclination correction
$\Phi = v + \omega$	argument of latitude
$v = \tan^{-1} \left\{ \frac{\sin v / \cos v}{\sqrt{1 - e^2} \sin E / (1 - e \cos E)} \right\}$	true anomaly
$= \tan^{-1} \left\{ \frac{(\cos E - e) / (1 - e \cos E)}{\sqrt{1 - e^2} \sin E / (1 - e \cos E)} \right\}$	
$t_k = t - s \Delta f t_{0e}$	t is Galileo system time and t_k is the actual total time difference between the time t and the epoch time t_{0e} (t_{0e} for the almanacs) which accounts for beginning or end of week crossovers
$M = E - e \sin(E)$	Kepler's equation for eccentric anomaly E
$M = M_0 + nt_k$	mean anomaly
$n = n_0 + \Delta n$	corrected mean motion
$n_0 = \sqrt{\mu / A^3}$	computed mean motion (rad/s)
$M_0, \Delta n, e, A^{1/2}, \Omega_0, i_0, \omega, \dot{\Omega}, di/dt, C_{us}, C_{uc}, C_{rs}, C_{rc}, C_{is}, C_{ic}$	ephemeris parameters transmitted in F/NAV signals page Types 2, 3 and 4, as well as I/NAV signals word Types 1, 2, 3 and 4 as indicated in 3.1.3.1.3.
t_{0e}	
$\pi = 3.1415926535898$	ratio of a circle's circumference to its diameter
$\mu = 3.986004418 \times 10^{14} \text{ m}^3/\text{s}^2$	geocentric gravitational constant
$\omega_E = 7.2921151467 \times 10^{-5} \text{ rad/s}$	mean angular velocity of the earth
$c = 299792458 \text{ m/s}$	speed of light in a vacuum

3.1.3.2.5 Ionospheric correction.

Note.— Receivers operating in single-frequency mode can use the single-frequency ionospheric correction algorithm described in document EUROCAE ED-259 Minimum Operational Performance Standard for Galileo/Global Positioning System/Satellite-based Augmentation System Airborne Equipment, Appendix J (any version).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 68

3.1.3.3 Aircraft elements

3.1.3.3.1 Galileo receiver

3.1.3.3.1.1 *Satellite tracking.* The receiver shall provide the capability to continuously track a minimum of four Galileo satellites and generate a position solution based upon those measurements.

3.1.3.3.1.2 *Doppler shift.* The receiver shall be able to compensate for dynamic Doppler shift effects on nominal Galileo signal carrier phase and OS code measurements. The receiver shall compensate for the Doppler shift that is unique to the anticipated application.

3.1.3.3.1.3 *Resistance to interference.* The receiver shall meet the requirements for resistance to interference as specified in 3.7.

3.1.3.3.1.4 *Application of clock and ephemeris data.* The receiver shall monitor the IODnav value and update ephemeris and clock data based upon a detected change in this parameter. To compute position and clock corrections, receivers shall use for each satellite, IODnav-tagged parameters corresponding to the same IODnav value. These parameters shall be retrieved from the most recent navigation data set received.

Note.— IODnav values are not necessarily incremented in steps of one. An IODnav with higher value does not necessarily mean that it tags more recent data. The only valid comparison between IODnav values is whether they are equal or not. For positioning, users can combine SIS from different satellites with different IODnav values, provided that the navigation parameters derived from each satellite are tagged by a unique IODnav value.

3.1.3.3.1.5 *Navigation data validity duration.* The receiver shall only use the ephemeris and clock corrections from a set of navigation data during a period of time no longer than four hours from the reference time of ephemeris (t_{0e}). The receiver shall not rely on performance commitments in Chapter 3, 3.7.3.1.3, if the age of t_{0e} exceeds four hours.

Note.— See Attachment D, 4.1.3.11 for guidance material on the age of t_{0e} .

3.1.3.4 TIME

3.1.3.4.1 *Galileo system time (GST).* The GST shall be a continuous timescale based on the definition of the second (according to the International System of Units, SI) whose origin/reference epoch (GST (T₀)) shall be defined as 13 seconds before 1999-08-22 00:00:00 UTC. The Galileo navigation message shall contain all necessary parameters to convert between GST and UTC.

Note.— See Attachment D, 4.1.3.9 for GST guidance material.

3.1.3.5 Coordinate system

3.1.3.5.1 The Galileo OS broadcast ephemeris shall determine the position of the transmitting antenna phase centre of a given satellite in the Galileo Terrestrial Reference Frame (GTRF) ECEF reference frame.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 69

3.1.3.5.2 The GTRF difference from the latest physical realization of the International Terrestrial Reference Frame (ITRF) shall not exceed 3 cm 95 per cent globally.

Note 1.— WGS-84 and GTRF are both realizations of ITRF. The difference between GTRF and WGS-84 used in GPS, is considered insignificant for aviation.

Note 2.— See Attachment D, 4.1.3.10 for additional information on GTRF.

3.1.4. BeiDou Navigation Satellite System (BDS) Open Service (OS) (B1I, B1C and B2a)

3.1.4.1 Non-Aircraft Elements

3.1.4.1.1 BDS RF characteristics

Note.— This section describes RF characteristics of the BDS B1I, B1C and B2a signals transmitted by BDS-3 MEO and IGSO satellites.

3.1.4.1.1.1 B1I, B1C and B2a common requirements

3.1.4.1.1.1.1 *Carrier phase noise.* The carrier phase noise spectral density of the unmodulated carrier on B1I, B1C and B2a shall be such that a third-order phase locked loop of 10 Hz one-sided noise bandwidth is able to track the carrier to an accuracy of 0.1 radian root mean square (RMS).

3.1.4.1.1.1.2 *Spurious emissions.* In-band spurious emissions shall be at least 50 dB below the unmodulated B1I, B1C and B2a carrier over the allocated channel bandwidth.

Note.— The allocated channel bandwidth for the B1I signal is 4.096 MHz. The allocated channel bandwidth for the B1C signal is 32.736 MHz. The allocated channel bandwidth for the B2a signal is 20.46 MHz.

3.1.4.1.1.1.3 *Data/code coherence.* The edge of each data symbol shall be aligned with the edge of the corresponding ranging code chip, and the start time of the first chip of the periodic ranging code shall be aligned with the start time of the data symbol bit. The edges of each secondary code chip shall be aligned with the edges of the primary code chip and the primary code first chip start time shall be aligned with the starting time of the secondary code chip.

3.1.4.1.1.2 B1I RF characteristics

3.1.4.1.1.2.1 *B1I correlation loss.* The correlation loss due to payload distortions shall not exceed 0.6 dB on B1I.

3.1.4.1.1.2.2 *B1I ranging code.* The chipping rate of the B1I ranging code shall be 2.046 megachips per second, and the length shall be 2 046 chips. The B1I ranging code (hereinafter referred to as C_{B1I}) shall be a balanced Gold code truncated with the last one chip. The Gold code shall be generated by means of Modulo-2 addition of G1 and G2 sequences, which are respectively derived from two 11-bit linear shift registers. The generator of C_{B1I} shall be as shown in Figure B-19.

Note.— Additional information concerning the B1I ranging code is given in the BeiDou Navigation Satellite System Signal In Space Interface Control Document Open Service Signal B1I (Version 3.0), dated February 2019 (hereinafter referred to as “BDS OS B1I ICD”), section 4.3.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I		BCAR-10	
	Technical provision for GNSS		Appendix-B	Page: 70

3.1.4.1.1.3 B1C RF characteristics

3.1.4.1.1.3.1 *B1C correlation loss.* The correlation loss due to payload distortions shall not exceed 0.3 dB on B1C.

3.1.4.1.1.3.2 *B1C signal generation.* The B1C signal shall comprise two components, known as B1C data component and B1C pilot component.

3.1.4.1.1.3.3 *B1C signal power split.* The B1C signal power shall be 1:3 split between the B1C data component and the B1C pilot component.

3.1.4.1.1.3.4 *B1C data ranging code ().* The B1C data ranging code sequence shall be a 10 230-chip length primary code repeated every 10 milliseconds.

Note.— Additional information concerning the B1C data primary code is given in BDS OS B1C ICD, section 5.2.1.

3.1.4.1.1.3.5 *B1C pilot ranging code (C_{B1C_pilot}).* The B1C pilot ranging code sequence shall be the Modulo-2 addition of a 10 230-chip length primary code repeated every 10 milliseconds and a 1 800-chip length secondary code repeated every 18 000 milliseconds.

Note. — Additional information concerning the B1C pilot primary code and secondary code is given in BDS OS B1C ICD, sections 5.2.1 and 5.2.2.

3.1.4.1.1.3.6 *B1C data component (S_{B1C_data}) generation.* The B1C data component shall be generated from the navigation message data (D_{B1C_data}) and the ranging code (C_{B1C_data}) modulated with the sine-phased BOC(1,1) subcarrier SC_{B1C_data} .

3.1.4.1.1.3.7 *B1C pilot component (S_{B1C_pilot}) generation.* The B1C pilot component shall be generated from the ranging code (C_{B1C_pilot}) modulated with the QMBOC(6, 1, 4/33) subcarrier SC_{B1C_pilot} . The subcarrier shall be composed of a BOC(1, 1) subcarrier and a BOC(6, 1) subcarrier, which shall be in phase quadrature with each other and have a power ratio of 29:4.

Note. — Additional information concerning B1C modulation is given in BDS OS B1C ICD, section 4.2.

3.1.4.1.1.4 B2a RF characteristics

3.1.4.1.1.4.1 *B2a correlation loss.* The correlation loss due to payload distortions shall not exceed 0.6 dB on B2a.

3.1.4.1.1.4.2 *B2a signal generation.* The B2a signal shall comprise two components known as B2a data component and B2a pilot component.

3.1.4.1.1.4.3 *B2a signal power split.* The B2a signal power shall be equally split between the B2a data component and the B2a pilot component.

3.1.4.1.1.4.4 *B2a data ranging code ().* The B2a data ranging code sequence shall be the Modulo-2 addition of a 10 230-chip length primary code repeated every 1 millisecond and a 5-chip length secondary code repeated every 5 milliseconds.

Note.— Additional information concerning B2a_data primary code and secondary code is given in BDS OS B2a ICD, sections 5.2.1 and 5.2.2.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

3.1.4.1.1.4.5 *B2a pilot ranging code (C_{B2a_pilot})*. The B2a pilot ranging code sequence shall be the Modulo-2 addition of a 10 230-chip length primary code repeated every 10 millisecond and a 100-chip length secondary code repeated every 100 milliseconds.

Note.— Additional information concerning *B2a_pilot* primary code and secondary code is given in *BDS OS B2a ICD*, sections 5.2.1 and 5.2.2.

3.1.4.1.1.4.6 *B2a data component (S_{B2a_data}) generation*. The B2a data component shall be BPSK(10) modulated from the navigation message data (D_{B2a_data}) and the ranging code (D_{B2a_data}).

3.1.4.1.1.4.7 *B2a pilot component (S_{B2a_pilot}) generation*. The B2a pilot component shall be BPSK(10) modulated from the ranging code only.

Note.— Additional information concerning *B2a* modulation is given in *BDS OS B2a ICD*, section 4.2.

3.1.4.1.2 DATA STRUCTURE

3.1.4.1.2.1 BII D1 message characteristics

3.1.4.1.2.1.1 *General*. The BII navigation message broadcast by BDS-3 MEOs and IGSOs BII signals (“D1 navigation message”) shall be modulated with 1 kbps secondary Neuman-Hofman (NH) code. The D1 navigation message shall be structured into superframes, frames and subframes. The frame structure of the D1 navigation message shall be as shown in Figure B-20.

Note.— Additional information concerning the NH code is given in *BDS OS BII ICD*, section 5.2.1.

3.1.4.1.2.1.2 *Superframe*. Every superframe shall contain 36 000 bits. Every superframe shall be composed of 24 frames (24 pages).

3.1.4.1.2.1.3 *Frame*. Every frame shall contain 1 500 bits. Every frame shall be composed of 5 subframes.

3.1.4.1.2.1.4 *Subframe*. Every subframe shall contain 300 bits. Every subframe shall be composed of 10 words. Every word shall contain 30 bits. Every word shall consist of navigation message data and parity bits.

3.1.4.1.2.1.5 *Data parity*. Word 1 of each subframe shall contain 26 information bits and 4 parity bits in the least significant bits (LSBs), and words 2 through 10 shall contain 22 information bits and 8 parity bits in the LSBs. Bose-Chaudhuri-Hocquenghem (BCH)(15,11,1) encoding shall be used for error control and interleaving.

Note.— Additional information concerning *BCH(15,11,1)* encoding is given in *BDS OS BII ICD*, section 5.1.3.

3.1.4.1.2.1.6 *Preamble*. Bits 1 through 11 of every subframe shall contain a preamble consisting of the sequence of bits “11100010010”.

3.1.4.1.2.1.7 *Subframe identification*. Bits 16 through 18 of every subframe shall contain the subframe identification, encoded as follows:

Code	001	010	011	100	101	110	111
Subframe identification	1	2	3	4	5	Reserved	Reserved

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 72

3.1.4.1.2.1.8 *Seconds-of-week (SOW)*. Bits 19 through 26 and bits 31 through 42 of each subframe of the D1 navigation message shall contain the 20-bit seconds-of-week (SOW), which is defined as the number of seconds that have occurred since the last Sunday, 00:00:00 BDT. The SOW count shall occur at the leading edge of the first preamble bit (MSB) of the subframe.

3.1.4.1.2.1.9 *Reserved bits*. Bits 12 through 15 of every subframe or page of a subframe shall be reserved.

3.1.4.1.2.2 *B1C message characteristics*

3.1.4.1.2.2.1 *General*. The B1C navigation message (B-CNAV1 navigation message) shall be broadcast as a sequence of frames. Each frame shall contain 1 800 symbols with a symbol rate of 100 symbols per second. Each frame shall consist of three subframes with the basic frame structure shown in Figure B-21.

3.1.4.1.2.2.2 *Subframe 1*. Subframe 1 shall contain 14 bits before BCH error correction encoding. After BCH (21,6) + BCH (51,8) encoding, its length shall be 72 symbols.

Note.— Additional information concerning BCH(21,6)+BCH(51,8) encoding is given in BDS OS B1C ICD, section 6.2.2.1.

3.1.4.1.2.2.3 *Subframe 2*. Subframe 2 shall contain 600 bits before low-density parity check (LDPC) encoding. The 576 MSBs of subframe 2 shall be included in the CRC calculation, and the 24 LSBs shall be the corresponding CRC bits. After 64-ary LDPC (200, 100) encoding, its length shall be 1 200 symbols.

Note.— Additional information concerning 64-ary LDPC (200, 100) encoding is given in BDS OS B1C ICD, section 6.2.2.2.

3.1.4.1.2.2.4 *Subframe 3*. Subframe 3 shall contain 264 bits before LDPC encoding. The 6 MSBs shall be the page type (PageID), the 24 LSBs shall be CRC bits, and the remaining 234 bits shall be message data. PageID and message data shall be included in the CRC calculation. After 64-ary LDPC (88,44) encoding, its length shall be 528 symbols. The frame structure of subframe 3 shall be as shown in Figure B-22.

Note.— Additional information concerning 64-ary LDPC (88,44) encoding is given in BDS OS B1C ICD, section 6.2.2.3.

3.1.4.1.2.2.5 *Interleaving*. After encoding, subframe 2 and subframe 3 shall be combined and interleaved using a block interleaver.

Note.— Additional information concerning interleaving is given in BDS OS B1C ICD, section 6.2.2.4.

3.1.4.1.2.3 *B2a message characteristics*

3.1.4.1.2.3.1 *General*. The B2a navigation message (“B-CNAV2 navigation message”) shall be broadcast as a sequence of frames. Each frame shall contain 600 symbols with a symbol rate per second. The B-CNAV2 basic frame structure shall be as shown in Figure B-23.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 73

3.1.4.1.2.3.2 *Frame structure.* Each frame shall consist of a 24-symbol preamble and a 288-bit navigation message before error correction encoding. After encoding by 64-ary LDPC (96,48), its length shall be 1 200 symbols.

Note.— Additional information concerning 64-ary LDPC (96,48) encoding is given in BDS OS B2a ICD, section 6.2.2.

3.1.4.1.2.3.2.1 *Preamble.* Each frame shall contain a preamble consisting of the sequence of bits “111000100100110111101000”.

3.1.4.1.2.3.2.2 *Navigation message.* Each frame shall contain 288 bits before LDPC encoding, including the 6-bit PRN code, 6-bit message type, 18-bit SOW, 234-bit message data and 24-bit CRC. PRN, message type, SOW, and message data shall be included in the CRC calculation. After 64-ary LDPC(96, 48) encoding, the frame length shall be 576 symbols.

3.1.4.1.3 *Data Content*

Note.— A full description of the data content of the words being transmitted is given in BDS OS B11 ICD, BDS OS B11 ICD and BDS OS B2a ICD.

3.1.4.1.3.1 *B11 data content*

3.1.4.1.3.1.1 The B11 D1 navigation data shall contain the information listed in Table B-42.

Note.— Additional information concerning B11 D1 content and application of the data is given in BDS OS B11 ICD, section 5.2.4.

Table B-42. B1I D1 navigation message content

<i>Subframe number</i>	<i>Page number</i>	<i>Data content</i>
1	N/A	Week number (WN), user range accuracy index (URAI), autonomous satellite health flag (SatH1), ionosphere model parameters ($\alpha_n, \beta_n, n=0-3$), equipment group delay differential (T_{GD1}, T_{GD2}), clock correction parameters (t_{oc}, a_0, a_1, a_2), age of data, clock (AODC), age of data, ephemeris (AODE)
2	N/A	Ephemeris parameters (1/2) ($\sqrt{A}, e, \Delta n, M_0, C_{uc}, C_{us}, C_{rc}, C_{rs}$)
3	N/A	Ephemeris parameters (2/2) ($t_{oe}, \omega, \Omega_0, \dot{\Omega}, i_0, IDOT, C_{ic}, C_{is}$)
4	1 - 24	Pnum, almanac parameters ($t_{oa}, \sqrt{A}, e, \omega, M_0, \Omega_0, \dot{\Omega}, \delta_i, a_0, a_1, AmEpID$)
5	1 - 6	
5	7	Pnum, health information for 19 satellites ($Hea_i, i=1-19$)
5	8	Pnum, health information for 11 satellites ($Hea_i, i=20-30$), week number of almanac (WN_a), t_{oa} .
5	9	Pnum, time parameters relative to GPS time (A_{0GPS}, A_{1GPS}), time parameters relative to GLONASS time (A_{0GLO}, A_{1GLO}), time parameters relative to Galileo time (A_{0Gal}, A_{1Gal})
5	10	Pnum, time parameters relative to UTC ($A_{0UTC}, A_{1UTC}, \Delta t_{LS}, \Delta t_{LSF}, WN_{LSF}, DN$)
5	11 - 23	Pnum, almanac parameters ($t_{oa}, \sqrt{A}, e, \omega, M_0, \Omega_0, \dot{\Omega}, \delta_i, a_0, a_1, AmID$)
5	24	Pnum, health information for 14 satellites ($Hea_i, i=31-43$)

3.1.4.1.3.1.2 *User range accuracy index (URAI)*. Bits 49 through 52 of subframe 1 of the D1 message shall contain the URAI. The range of URAI shall be from 0 to 15. The user range accuracy (URA) shall be used to describe the signal-in-space accuracy (SISA) in metres. The relationship between URAI and URA shall be as shown in Table B BDS-2.

Note.— Additional information concerning URAI is given in BDS OS B1I ICD, section 5.2.4.5 and section 5.2.3, Figure 5-8.

Table B-43. Relationship between URAI and URA

<i>Code</i>	<i>URAI</i>	<i>URA range (m, 1σ)</i>
0000	0	0.00 < URA ≤ 2.40
0001	1	2.40 < URA ≤ 3.40
0010	2	3.40 < URA ≤ 4.85
0011	3	4.85 < URA ≤ 6.85
0100	4	6.85 < URA ≤ 9.65
0101	5	9.65 < URA ≤ 13.65
0110	6	13.65 < URA ≤ 24.00
0111	7	24.00 < URA ≤ 48.00
1000	8	48.00 < URA ≤ 96.00
1001	9	96.00 < URA ≤ 192.00
1010	10	192.00 < URA ≤ 384.00
1011	11	384.00 < URA ≤ 768.00
1100	12	768.00 < URA ≤ 1 536.00
1101	13	1 536.00 < URA ≤ 3 072.00
1110	14	3 072.00 < URA ≤ 6 144.00
1111	15	URA > 6 144.00

3.1.4.1.3.1.3 *Autonomous satellite health flag (SatH1)*. Bit 43 of subframe 1 of the D1 message shall provide SatH1. A value of “0” shall indicate that the broadcasting satellite is healthy and a value of “1” shall indicate that the broadcasting satellite is unhealthy.

Note.— *Additional information concerning SatH1 is given in BDS OS BII ICD, section 5.2.4.6 and section 5.2.3, Figure 5-8.*

3.1.4.1.3.1.4 *Satellite clock correction parameter t_{oc}* shall be broadcast in the D1 navigation message. The value of t_{oc} shall monotonically increase over the week and shall change if any of the clock parameters change.

Note.— *The update of the clock parameters always starts at the beginning of a superframe.*

3.1.4.1.3.1.5 *Satellite ephemeris parameter t_{oe}* shall be broadcast in the D1 navigation message. The value of t_{oe} shall monotonically increase over the week and shall change if any of the ephemeris parameters change. If t_{oe} changes, then t_{oc} shall also change.

Note.— *The update of the ephemeris parameters always starts at the beginning of a superframe.*

3.1.4.1.3.1.6 *Page number (Pnum)*. Both subframe 4 and subframe 5 shall have 24 pages which shall be identified through the page number (Pnum) contained in bits 44 through 50 of the subframes.

3.1.4.1.3.1.7 *Identification of expanded almanacs (AmEpID)*. Bits 291 through 292 of pages 1 through 24 of subframe 4 and pages 1 to 6 of subframe 5 shall contain AmEpID. A binary value of “11” of AmEpID shall indicate that pages 11 through 23 of subframe 5 are used to broadcast the almanac parameters for SV ID 31 through 63, and page 24 of subframe 5 is used to broadcast the satellite health information for SV ID 31 through 63. Otherwise, pages 11 through 24 of subframe 5 shall be reserved.

3.1.4.1.3.1.8 *Identification of time-sharing broadcasting (AmID)*. Bits 291 through 292 of pages 11 through 23 of subframe 5 and bits 216 through 217 of page 24 of subframe 5 shall provide AmID. AmID shall be used combining with AmEpID and Pnum to indicate the PRN of the satellite transmitting the almanac parameters in the Pnum page. AmID shall only be used when AmEpID has a binary value of “11”. The broadcasting scheme for the almanac parameters of SV ID 31 through 63 shall be as shown in Table B BDS-3.

Table B-44. Broadcasting scheme for the almanac parameters of PRNs 31 through 63

<i>AmEpID</i>	<i>AmID</i>	<i>Pnum</i>	<i>PRN</i>
	01	11 - 23	31 - 43
	10	11 - 23	44 - 56
11	11	11 - 17	57 - 63
	11	18 - 23	Reserved
	00	11 - 23	Reserved

3.1.4.1.3.2 *B1C and B2a data content*

3.1.4.1.3.2.1 The B-CNAV1 data broadcasted on B1C shall contain the information listed in Table B-45. The B-CNAV2 data broadcasted on B2a shall contain the message types and data content listed in Table B-46.

Note 1.— Additional information concerning B-CNAV1 data content and application of the data is given in BDS OS B1C ICD, section 7.

Note 2.— Additional information concerning B-CNAV2 data content and application of the data is given in BDS OS B2a ICD, section 7.

Table B-45. B1C navigation message information contents

<i>Subframe number</i>	<i>Data content</i>	
1	PRN, SOH	
2	WN, HOW, IODC (issue of data, clock), IODE (issue of data, ephemeris)	
	Data blocks*	Ephemeris I* (t_{oe} , SatType, ΔA , \dot{A} , Δn_0 , $\Delta \dot{n}_0$, M_0 , e , ω)
		Ephemeris II* (Ω_0 , i_0 , $\dot{\Omega}$, \dot{i}_0 , C_{is} , C_{ic} , C_{rs} , C_{rc} , C_{us} , C_{uc})
		Clock correction parameters* (t_{oc} , a_0 , a_1 , a_2)
	TGDB2ap, ISCB1Cd, TGDB1Cp, Rev, CRC	
3**	Page Type 1 (PageID, health status(HS), data integrity flag (DIF), signal integrity flag (SIF), accuracy integrity flag (AIF), signal-in-space monitored accuracy index (SISMAI)***, SISAIoe, SISAIoc*, ionospheric delay correction model parameters*, BDT-UTC time offset parameters*)	
	Page Type 2 (PageID, HS, DIF, SIF, AIF, SISMAI***, SISAIoc*, WNa, t_{oa} , reduced almanac*)	
	Page Type 3 (PageID, HS, DIF, SIF, AIF, SISMAI***, SISAIoe, earth orientation parameters (EOP), BDT-GNSS time offset (BGTO) parameters)	
	Page Type 4 (PageID, HS, DIF, SIF, AIF, SISMAI***, SISAIoc*, midi almanac*)	
<p>* Data blocks containing a set of parameters.</p> <p>** At most 63 page types can be defined for subframe 3. Currently, four valid page types have been defined: 1, 2, 3 and 4.</p> <p>*** SISMA broadcast in B-CNAV1 is reserved for future use.</p>		

Table B-46. B2a message types and the data content

	<i>Message type**</i>	<i>Data content</i>
1	10	PRN, MesType, SOW, WN, DIF(B2a), SIF(B2a), AIF(B2a), SISMAI****, DIF(B1C), SIF(B1C), IODE, ephemeris I*
2	11	PRN, MesType, SOW, HS, DIF(B2a), SIF(B2a), AIF(B2a), SISMAI****, DIF(B1C), SIF(B1C), ephemeris II*
3	30	PRN, MesType, SOW, HS, DIF(B2a), SIF(B2a), AIF(B2a), SISMAI****, DIF(B1C), SIF(B1C), clock correction parameters*, IODC, TGDB2ap, ISC _{B2ad} , ionospheric delay correction model parameters*, TGDB1cp
4	31	PRN, MesType, SOW, HS, DIF(B2a), SIF(B2a), AIF(B2a), SISMAI****, DIF(B1C), SIF(B1C), clock correction parameters*, IODC, WNa, toa, reduced almanac parameters*
5	32	PRN, MesType, SOW, HS, DIF(B2a), SIF(B2a), AIF(B2a), SISMAI****, DIF(B1C), SIF(B1C), clock correction parameters*, IODC, EOP
6	33	PRN, MesType, SOW, HS, DIF(B2a), SIF(B2a), AIF(B2a), SISMAI****, DIF(B1C), SIF(B1C), AIF(B1C), clock correction parameters*, BGTO parameters*, reduced almanac parameters*, IODC, WNa, toa
7	34	PRN, MesType, SOW, HS, DIF(B2a), SIF(B2a), AIF(B2a), SISMAI****, DIF(B1C), SIF(B1C), SISAIoc*, clock correction parameters*, IODC, BDT-UTC time offset parameter*
8	40	PRN, MesType, SOW, HS, DIF(B2a), SIF(B2a), AIF(B2a), SISMAI****, DIF(B1C), SIF(B1C), SISAIoc, SISAIoc*, midi almanac parameters*
<p>* Data blocks containing a set of parameters.</p> <p>** At most 63 message types can be defined for the B-CNAV2 navigation message. Currently, eight valid message types have been defined: 10, 11, 30, 31, 32, 33, 34 and 40.</p> <p>*** The broadcast order of the B-CNAV2 message types may be dynamically adjusted, however Message Types 10 and 11 are broadcast continuously together.</p> <p>**** SISMAI broadcast in B-CNAV2 is reserved for future use.</p>		

3.1.4.1.3.2.2 *Page type*. Page ID shall be used to identify the page types of subframe 3 in B-CNAV1. It shall be a 6-bit unsigned integer. Its definition shall be as shown in Table B-47.

Table B-47. Page type definition

<i>Page ID (binary)</i>	<i>Page type</i>
000000	Invalid
000001	1
000010	2
000011	3
000100	4
Others	Reserved

3.1.4.1.3.2.3 *Message type (MesType)*. Message type shall be used to identify the message types of the B-CNAV2 frames. It shall be a 6-bit unsigned integer. Its definition shall be as shown in Table B-48.

Table B-48. Message type definition

<i>Message Type (Binary)</i>	<i>Message type</i>
000000	Invalid
001010	10
001011	11
011110	30
011111	31
100000	32
100001	33
100010	34
101000	40
Others	Reserved

3.1.4.1.3.2.4 *Issue of data*

Note 1.— Additional information concerning B1C issue of data is given in BDS OS B1C ICD, section 7.4.1, Table 7-3 and section 7.4.2, Table 7-4.

Note 2.— Additional information concerning B2a issue of data is given in BDS OS B2a ICD, section 7.4.1, Table 7-3 and section 7.4.2, Table 7-4.

3.1.4.1.3.2.4.1 *Issue of data, ephemeris (IODE)*. IODE shall indicate the issue number of a set of ephemeris parameters. The IODE value shall be updated when any ephemeris parameter is updated. The IODE values shall indicate the range of the ephemeris data age. The ephemeris data age shall be defined as the offset between the ephemeris parameters reference time (t_{oe}) and the last measured time for generating the ephemeris parameters. The values of IODE shall not be repeated within any 24 hours. The relationship between the IODE values and the ephemeris data age shall be as in Table B-49.

Table B-49. Relationship between the IODE values and the ephemeris data age

<i>IODE value</i>	<i>Ephemeris data age</i>
0 – 59	Less than 12 hours
60 – 119	12 hours – 24 hours
120 – 179	1 day – 7 days
180 – 239	Reserved
240 – 255	More than 7 days

3.1.4.1.3.2.4.2 *Issue of data, clock (IODC)*. IODC shall indicate the issue number of a set of clock correction parameters. The IODC value shall be updated when any clock correction parameter is updated. The IODC values shall indicate the range of the clock correction data age. The clock correction data age shall be defined as the offset between the clock correction parameters reference time (t_{oc}) and the last measured time for generating the clock correction parameters. The range of the clock correction data age shall be defined by the 2 MSBs of IODC together with the 8 LSBs of IODC. The values of IODC shall not be repeated within any 24 hours. The relationship between the IODC values and the clock correction data age shall be as in Table B-50.

Table B-50. Relationship between the IODC values and the clock correction data age

<i>2 MSBs of IODC</i>	<i>8 LSBs of IODC</i>	<i>Clock correction data age</i>
00	0 – 59 60 – 119 120 – 179 180 – 239 240 – 255	Less than 12 hours 12 hours – 24 hours 1 day – 7 days Reserved More than 7 days
01	0 – 59 60 – 119 120 – 179 180 – 239 240 – 255	Less than 12 hours Less than 12 hours Less than 1 day Reserved No more than 7 days
10	0 – 59 60 – 119 120 – 179 180 – 239 240 – 255	More than 12 hours More than 24 hours More than 7 days Reserved More than 7 days
11	Reserved	Reserved

3.1.4.1.3.2.5 *Satellite health status.* Satellite health status (SHS) shall indicate the health status of the transmitting satellite. The definitions of the SHS parameter shall be as shown in Table B-51.

Note 1.— Additional information concerning B1C SHS is given in BDS OS B1C ICD, section 7.14, Table 7-22.

Note 2.— Additional information concerning B2a SHS is given in BDS OS B2a ICD, section 7.14, Table 7-22.

Table B-51. Definitions of the SHS parameter

<i>SHS value</i>	<i>Definition</i>	<i>Description</i>
0	The satellite is healthy	The satellite provides services
1	The satellite is unhealthy or under test	The satellite does not provide services
2	Reserved	Reserved
3	Reserved	Reserved

3.1.4.1.3.2.6 *Satellite integrity status.* The satellite integrity status shall be conveyed by two parameters: data integrity flag (DIF) and signal integrity flag (SIF). Each of them shall occupy 1 bit and their definitions shall be as shown in Table B-52.

Note 1.— Additional information concerning the B1C satellite integrity status flag is given in BDS OS B1C ICD, section 7.15, Table 7-23.

Note 2.— Additional information concerning the B2a satellite integrity status flag is given in BDS OS B2a ICD, section 7.15, Table 7-23.

Table B-52. Definitions of the satellite integrity status flag parameters

<i>Parameter</i>	<i>Value</i>	<i>Definition</i>
DIF	0	The error of message parameters broadcast in this signal does not exceed the predictive accuracy
	1	The error of message parameters broadcast in this signal exceeds the predictive accuracy
SIF	0	This signal is normal
	1	This signal is abnormal

3.1.4.1.3.2.7 *Satellite signal-in-space health status (SISHS)*

3.1.4.1.3.2.7.1 BDS OS signal-in-space health status (SISHS) shall take one of the three states:

- a) healthy: the signal meets the minimum service performance specified in this document;
- b) unhealthy: the signal is not providing services or is being tested; and
- c) marginal: the signal is neither of the two previous states.

3.1.4.1.3.2.7.2 The B1C and B2a SISHS shall be indicated by the combination of four SIS flags: HS, SIF and DIF. The mapping between the values of the three flags and B1C/B2a SISHS shall be as shown in Table B-53.

Table B-53. The mapping between the values of the three flags and B1C/B2a SISHS

<i>B1C/B2a SISHS</i>	<i>HS</i>	<i>SIF</i>	<i>DIF</i>
Healthy	0	0	0
Marginal	0	0	1
	2/3	0	0
Unhealthy	Any value	1	0/1
	1	0/1	0/1

3.1.4.1.3.2.8 *Signal-in-space accuracy (SISA) indices.* The SISA shall describe the predictive accuracy of the orbital parameters and clock correction parameters broadcast in the navigation message. It shall comprise the along-track and cross-track accuracy of the satellite orbit ($SISA_{oe}$) as well as the satellite orbital radius and satellite clock correction accuracy ($SISA_{oc}$). The SISA index parameters listed below shall be used to calculate $SISA_{oe}$ and $SISA_{oc}$ and shall be broadcast in B-CNAV1 Subframe 3 for B1C and B-CNAV2 Message Type 40 for B2a, respectively:

- a) $SISAI_{oe}$ which is a signed, two's complement integer in the range of +15 to -16 shall indicate the combined satellite along-track and cross-track orbit accuracy as shown in Table B-54;
- b) $SISAI_{ocb}$ which is a signed, two's complement integer in the range of +15 to -16 shall indicate the combined satellite orbit radial and satellite clock bias accuracy as shown in Table B-54;
- c) $SISAI_{oc1}$ with an integer value in the range of 0 to 7 shall indicate the satellite clock drift accuracy;
- d) $SISAI_{oc2}$ with an integer value in the range of 0 to 7 shall indicate the satellite clock drift rate accuracy; and
- e) *top* shall indicate the time of week for data prediction.

Note 1.— Additional information concerning the SISA index parameters is given in BDS OS B1C ICD, section 7.16.

Note 2.— Additional information concerning the SISA index parameters is given in BDS OS B2a ICD, section 7.16.

Table B-54. Mapping between $SISA_{oe}$ index and $SISA_{oe}$

$SISA_{oe}$ index	$SISA_{oe}$ (metres)
15	$6\ 144.00 < SISA_{oe}$ (or no accuracy prediction is available)
14	$3\ 072.00 < SISA_{oe} \leq 6\ 144.00$
13	$1\ 536.00 < SISA_{oe} \leq 3\ 072.00$
12	$768.00 < SISA_{oe} \leq 1\ 536.00$
11	$384.00 < SISA_{oe} \leq 768.00$

3.1.4.2 DEFINITIONS OF PROTOCOLS FOR DATA APPLICATION

Note.— This section defines the inter-relationships of the data broadcast message parameters. It provides definitions of parameters that are not transmitted but are used by either or both non-aircraft and aircraft elements, and that define terms applied to determine the navigation solution and its integrity.

3.1.4.2.1 Parity algorithms.

3.1.4.2.1.1 The D1 message uses BCH(15,11,1) encoding as parity algorithms as indicated in section 3.1.4.1.2.1.5.

3.1.4.2.1.2 The B-CNAV1 message and the B-CNAV2 message use a 24-bit CRC. The CRC shall be calculated in accordance with 3.7, with the following generator polynomial:

$$G(X) = \sum_{i=0}^{24} g_i X^i$$

where:

$G_i = 1$ for 0, 1, 3, 4, 5, 6, 7, 10, 11, 14, 17, 18, 23, 24 and 0 otherwise.

3.1.4.2.2 Satellite clock correction parameters.

3.1.4.2.2.1 BDS system time t shall be computed as follows:

$$t = t_{sv} - \Delta t_{sv}$$

where:

$t =$ BDT in seconds at time of signal transmission;

$t_{sv} =$ the effective satellite ranging code phase time in seconds at time of signal transmission; and

$\Delta t_{sv} =$ the offset of satellite ranging code phase time in seconds defined as:

$$\Delta t_{sv} = a_0 + a_1(t - t_{oc}) + a_2(t - t_{oc})^2 + \Delta t_r$$

where:

a_0 , a_1 and a_2 and t_{oc} are parameters transmitted in D1 navigation message subframe 1, in B-CNAV1 subframe 2 and

B-CNAV2 message Types 30, 31, 32, 33 and 34; and

Δt_r is the relativistic effect correction term defined as:

$$\Delta t_r = F \cdot e \cdot \sqrt{A} \cdot \sin E_k$$

where:

e , \sqrt{A} , E_k are parameters that can get from D1 navigation message subframe 2 and subframe 3, from B-CNAV1 subframe 2 and B-CNAV2 message Types 10 and 11;

$F = -2\mu_1/2/c^2$;

$\mu = 3.986004418 \times 10^{14} \text{ m}^3/\text{s}^2$ is the value of the earth's universal gravitational constant; and

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I		BCAR-10	
	Technical provision for GNSS		Appendix-B	Page: 86

$c = 2.99792458 \times 10^8$ m/s is the speed of light.

3.1.4.2.2.2 BDS system time related to UTC (NTSC) time. BeiDou system time offset with respect to UTC shall be determined by using B1I data, B1C data or B2a data.

Note. — Additional information concerning time parameters and algorithms relating BeiDou system time to UTC is given in section 5.2.4.18, BDS OS B1I ICD; section 7.12, BDS OS B1C ICD; and section 7.12, BDS OS B2a ICD.

3.1.4.2.3 Satellite position.

3.1.4.2.3.1 B1I satellite position solution. The current satellite position shall be computed as shown in Table B-56.

Note 1. — The current satellite position is defined using ephemeris parameters. The ephemeris parameters (t_{oe} , e , ω , Δn , M_0 , Ω_0 , Ω , i_0 , $IDOT$, C_{uc} , C_{us} , C_{rc} , C_{rs} , C_{ic} , C_{is}) used in the B1I satellite position solution are parameters transmitted by D1 navigation message subframe 2 and subframe 3.

Note 2.— Additional information concerning ephemeris parameters and algorithms is given in BDS OS B1I ICD, section 5.2.4.12.

Table B-56. BII ephemeris algorithm

Computation steps	Description
$\mu = 3.986004418 \times 10^{14} \text{ m}^3/\text{s}^2$	Value of the earth's universal gravitational constant in BDCS
$\dot{\Omega}_e = 7.2921150 \times 10^{-5} \text{ rad/s}$	Value of the earth's rotation rate in BDCS
$\pi = 3.1415926535898$	Ratio of a circle's circumference to its diameter
$A = (\sqrt{A})^2$	Computed semi-major axis
$n_0 = \sqrt{\frac{\mu}{A^3}}$	Computed mean motion (radians/s)
$t_k = t - t_{oe}^*$	Computed time from ephemeris reference epoch
$n = n_0 + \Delta n$	Corrected mean motion
$M_k = M_0 + nt_k$	Computed mean anomaly
$M_k = E_k - e \sin E_k$	Kepler's equation for eccentric anomaly (radians)
$\begin{cases} \sin v_k = \frac{\sqrt{1-e^2} \sin E_k}{1-e \cos E_k} \\ \cos v_k = \frac{\cos E_k - e}{1-e \cos E_k} \end{cases}$	Computed true anomaly
$\phi_k = v_k + \omega$	Computed argument of latitude
$\begin{cases} \delta u_k = C_{us} \sin(2\Phi_k) + C_{uc} \cos(2\Phi_k) \\ \delta r_k = C_{rs} \sin(2\Phi_k) + C_{rc} \cos(2\Phi_k) \\ \delta i_k = C_{is} \sin(2\Phi_k) + C_{ic} \cos(2\Phi_k) \end{cases}$	Argument of latitude correction
	Radius correction
	Inclination correction
$u_k = \phi_k + \delta u_k$	Corrected argument of latitude parameters
$r_k = A(1 - e \cos E_k) + \delta r_k$	Corrected radius
$i_k = i_0 + \text{IDOT} \cdot t_k + \delta i_k$	Corrected inclination
$\begin{cases} x_k = r_k \cos u_k \\ y_k = r_k \sin u_k \end{cases}$	Computed satellite positions in orbital plane
$\Omega_k = \Omega_0 + (\dot{\Omega} - \dot{\Omega}_e)t_k - \dot{\Omega}_e t_{oe}$	Corrected longitude of ascending node in BDCS
$\begin{cases} X_k = x_k \cos \Omega_k - y_k \sin \Omega_k \\ Y_k = x_k \sin \Omega_k + y_k \cos \Omega_k \\ Z_k = y_k \sin i_k \end{cases}$	MEO/IGSO satellite coordinates in BDCS
<p>* In the equations, "t" is the time of signal transmission in BDT. "t_k" is the total time difference between t and ephemeris reference time t_{oe}, after accounting for beginning or end-of-week crossovers by subtracting 604 800 seconds from t_k if t_k is greater than 302 400 or adding 604 800 seconds to t_k if t_k is less than -302 400 seconds.</p>	

3.1.4.2.3.2 *B1C and B2a satellite position solution.* The current satellite position shall be computed as shown in Table B-57.

Note 1.— The current satellite position is defined using ephemeris parameters. The ephemeris parameters (toe, SatType, ΔA, A, Δn0, Δn0, M0, e, ω, Ω0, i0, Ω, i0, Cis, Cic, Crs, Crc, Cus, Cuc) used in the B1C and B2a satellite position solution are parameters transmitted by B-CNAV1 navigation message subframe 2 and 3, or by B-CNAV2 navigation message Type 10 and message Type 11.

Note 2.— Additional information concerning ephemeris parameters and algorithms is given in BDS OS B1C ICD, section 7.7, and in BDS OS B2a ICD, section 7.7.

Table B-57. B1C/B2a ephemeris algorithm

Computation steps	Description
$\mu = 3.986004418 \times 10^{14} \text{ m}^3/\text{s}^2$	Geocentric gravitational constant of BDCS
$\dot{\Omega}_e = 7.2921150 \times 10^{-5} \text{ rad/s}$	Earth's rotation rate of BDCS
$\pi = 3.1415926535898$	Ratio of a circle's circumference to its diameter
$t_k = t - t_{oe} **$	Time from ephemeris reference time
$A_0 = A_{ref} + \Delta A_0$	Semi-major axis at reference time
$A_k = A_0 + (\dot{A})t_k$	Semi-major axis
$n_0 = \sqrt{\frac{\mu}{A_0^3}}$	Computed mean motion (radians/s) at reference time
$\Delta n_A = \Delta n_0 + 1/2 \Delta \dot{n}_0 t_k^2$	Mean motion difference from computed value
$n_A = n_0 + \Delta n_A$	Corrected mean motion
$M_k = M_0 + n_A t_k$	Mean anomaly
$M_k = E_k - e \sin E_k$	Kepler's equation for eccentric anomaly (radians)
$\begin{cases} \sin v_k = \frac{\sqrt{1 - e^2} \sin E_k}{1 - e \cos E_k} \\ \cos v_k = \frac{\cos E_k - e}{1 - e \cos E_k} \end{cases}$	True anomaly
$\Phi_k = V_k + \omega$	Argument of latitude
$\begin{cases} \delta u_k = C_{us} \sin(2\Phi_k) + C_{uc} \cos(2\Phi_k) \\ \delta r_k = C_{rs} \sin(2\Phi_k) + C_{rc} \cos(2\Phi_k) \\ \delta i_k = C_{is} \sin(2\Phi_k) + C_{ic} \cos(2\Phi_k) \end{cases}$	Argument of latitude correction Radius correction Inclination correction
Computation steps	Description
$u_k = \Phi_k + \delta u_k$	Corrected argument of latitude
$r_k = A_k (1 - e \cos E_k) + \delta r_k$	Corrected radius
$i_k = i_0 + \dot{i}_0 \cdot t_k + \delta i_k$	Corrected inclination
$\begin{cases} x_k = r_k \cos u_k \\ y_k = r_k \sin u_k \end{cases}$	Position in orbital plane
$\Omega_k = \Omega_0 + (\dot{\Omega} - \dot{\Omega}_e) t_k - \dot{\Omega}_e t_{oe}$	Corrected longitude of ascending node
$\begin{cases} X_k = x_k \cos \Omega_k - y_k \sin \Omega_k \\ Y_k = x_k \sin \Omega_k + y_k \cos \Omega_k \\ Z_k = y_k \sin i_k \end{cases}$	Coordinate of the MEO/IGSO satellite antenna phase centre in BDCS
<p>* Semi-major axis reference value: $A_{ref} = 27906100\text{m}$ (MEO). $A_{ref} = 42162200\text{m}$ (IGSO/GEO).</p> <p>** In the equation, t is the BDT time of signal transmission, i.e., the BDT time corrected for transit time; t_k is the total time difference between t and the ephemeris reference time t_{oe}, after accounting for beginning or end-of-week crossovers by subtracting 604 800 seconds from t_k if t_k is greater than 302 400 or adding 604 800 seconds to t_k if t_k is less than -302 400 seconds.</p>	

3.1.4.2.4 Ionospheric delay correction.

3.1.4.2.4.1 *B1I ionospheric delay correction.* The B1I ionospheric delay correction shall be computed as shown in Table B-58.

Table B-58. Single-frequency ionospheric delay computation for B1I

Computation steps	Description
t_E	t_E is the SOW in BDT computed by user.
$\Psi = \frac{\pi}{2} - E - \arcsin\left(\frac{R}{R+h} \cdot \cos E\right)$	Ψ is the earth's central angle in radians between the user location and the ionospheric pierce point (IPP). R is the mean radius of the earth (6 378 km). E is the satellite elevation from the user's location in radians. H is the height of ionosphere (375 km).
$\Phi_M = \arcsin(\sin\Phi_u \cdot \cos\Psi + \cos\Phi_u \cdot \sin\Psi \cdot \cos A)$	Φ_M is the geographic latitude of the earth projection of the IPP in radians; A is the satellite azimuth from the user location in radians.
$\lambda_M = \lambda_u + \arcsin\left(\frac{\sin\Psi \cdot \sin A}{\cos\Phi_M}\right)$	λ_M is the geographic longitude of the earth projection of the IPP in radians.
$t = (t_E + \lambda_M \times 43200/\pi) \text{ [modulo } 86400\text{]}$	t is the local time (range 0 – 86 400 s) for the earth projection of the IPP.
$A_2 = \begin{cases} \sum_{n=0}^3 \alpha_n \left \frac{\Phi_M}{\pi}\right ^n, & A_2 \geq 0 \\ 0, & A_2 < 0 \end{cases}$	A_2 is the amplitude of the Klobuchar cosine curve in the daytime computed from the α_n ; α_n : coefficients broadcast in D1 navigation message subframe 3.
$A_4 = \begin{cases} 172800, & A_4 \geq 172800 \\ \sum_{n=0}^3 \beta_n \left \frac{\Phi_M}{\pi}\right ^n, & 172800 > A_4 \geq 72000 \\ 72000, & A_4 < 72000 \end{cases}$	A_4 is the period of the cosine curve in seconds; β_n are the coefficients broadcast in D1 navigation message subframe 3.
$I_2'(t) = \begin{cases} 5 \times 10^{-9} + A_2 \cos\left[\frac{2\pi(t - 50400)}{A_4}\right], & t - 50400 < A_4/4 \\ 5 \times 10^{-9}, & t - 50400 \geq A_4/4 \end{cases}$	$I_2'(t)$ is the vertical ionospheric delay correction.
$I_{B1I}(t) = \frac{1}{\sqrt{1 - \left(\frac{R}{R+h} \cdot \cos E\right)^2}} \cdot I_2'(t)$	$I_{B1I}(t)$ is the ionospheric delay along the B1I propagation path.

3.1.4.2.4.2 B1C and B2a ionospheric delay correction.

3.1.4.2.4.2.1 Single-frequency ionospheric delay correction. The B1C or B2a ionospheric delay correction shall be computed as shown in Table B-59.

Table B-59. Single-frequency ionospheric delay computation for B1C and B2a

<i>Computation steps</i>	<i>Description</i>
$\psi = \frac{\pi}{2} - E - \arcsin\left(\frac{R_e}{R_e + H_{ion}} \cdot \cos E\right)$	<p>ψ indicates the earth's central angle between the user position and the IPP</p> <p>E is the elevation angle between the user and satellite (in radians)</p> <p>H_{ion} is the altitude of the ionospheric single-layer shell (400 km)</p> <p>R_e is the mean radius of the earth (6 378 km)</p>
$\begin{cases} \varphi_g = \arcsin(\sin \varphi_u \cdot \cos \psi + \cos \varphi_u \cdot \sin \psi \cdot \cos A) \\ \lambda_g = \lambda_u + \arctan\left(\frac{\sin \psi \cdot \sin A \cdot \cos \varphi_u}{\cos \psi - \sin \varphi_u \cdot \sin \varphi_g}\right) \end{cases}$	<p>φ_g is the geographic latitude of the earth projection of the IPP</p> <p>λ_g is the geographic longitude of the earth projection of the IPP</p> <p>φ_u is the user geographic latitude</p> <p>λ_u is the user geographic longitude</p> <p>A is the azimuth angle between the user and the satellite (in radians)</p>
$\begin{cases} \varphi_m = \arcsin(\sin \varphi_M \cdot \sin \varphi_g + \cos \varphi_M \cdot \cos \varphi_g \cdot \cos(\lambda_g - \lambda_M)) \\ \lambda_m = \arctan\left(\frac{\cos \varphi_g \cdot \sin(\lambda_g - \lambda_M) \cdot \cos \varphi_M}{\sin \varphi_M \cdot \sin \varphi_m - \sin \varphi_g}\right) \end{cases}$	<p>φ_m is the geomagnetic latitude of the earth projection of the IPP in the earth-fixed reference frame</p> <p>λ_m is the geomagnetic longitude of the earth projection of the IPP in the earth-fixed reference frame</p> <p>λ_M is the geographic longitude of the north magnetic pole: $\lambda_M = \frac{-72.58^\circ}{180^\circ} \cdot \pi \text{ rad}$</p> <p>$\varphi_M$ is the geographic latitude of the north magnetic pole: $\varphi_M = \frac{-80.27^\circ}{180^\circ} \cdot \pi \text{ rad}$</p>
$S_{ion} = \pi \cdot (1 - 2 \cdot (t - \text{int}(t)))$	<p>S_{ion} is the mean geographic longitude of the sun (in radians)</p> <p>t is the time (in days) of the calculation epoch expressed by Modified Julian Date (MJD)</p> <p>$\text{int}(\cdot)$ is rounding down</p>
$\begin{cases} \varphi' = \varphi_m \\ \lambda' = \lambda_m - \arctan\left(\frac{\sin(S_{ion} - \lambda_M)}{\sin \varphi_M \cdot \cos(S_{ion} - \lambda_M)}\right) \end{cases}$	<p>φ' is the geomagnetic latitude of the IPP in the solar-fixed reference frame</p> <p>λ' is the geomagnetic longitude of the IPP in the solar-fixed reference frame</p>

<i>Computation steps</i>	<i>Description</i>
$\begin{cases} P_{n,n}(\sin\varphi') = (2n-1)!! (1 - (\sin\varphi')^2)^{n/2}, n = m \\ P_{n,m}(\sin\varphi') = \sin\varphi' \cdot (2m+1) \cdot P_{n,m}(\sin\varphi'), n = m+1 \\ P_{n,m}(\sin\varphi') = \frac{(2n-1) \cdot \sin\varphi' \cdot P_{n-1,m}(\sin\varphi') - (n+m-1) \cdot P_{n-2,m}(\sin\varphi')}{n-m}, \text{else} \end{cases}$	<p>$P_{n,m}$ is the classic, un-normalized Legendre function</p> <p>$(2n-1)!! = (2n-1) \cdot (2n-3) \cdots$</p> <p>$P_{0,0}(\sin\varphi') = 1$</p>
$\begin{cases} N_{n,m} = \sqrt{\frac{(n-m)! \cdot (2n+1) \cdot (2-\delta_{0,m})}{(n+m)!}} \\ \delta_{0,m} = \begin{cases} 1, m = 0 \\ 0, m > 0 \end{cases} \end{cases}$	<p>$N_{n,m}$ is the normalization function</p>

$T_{ion} = M_F \cdot \frac{40.28 \times 10^{16}}{f^2} \cdot VTEC$	<p>T_{ion} is the ionospheric delay correction</p>

Table B-60 Values of n_i and m_i

i	1	2	3	4	5	6	7	8	9
n_i/m_i	0/0	1/0	1/1	1/-1	2/0	2/1	2/-1	2/2	2/-2

Note.— Additional information concerning ionospheric delay correction model parameters broadcast on B1C and B2a and the user algorithms are given in BDS OS B1C ICD, section 7.8.2, Table 7-12, and in BDS OS B2a ICD, section 7.8.2, Table 7-12.

3.1.4.2.4.2.2 Dual-frequency ionospheric delay correction

For the dual-frequency user applying the B1C and B2a signals, the effect of the ionospheric delay shall be corrected by using the dual-frequency ionosphere-free pseudo-range.

The dual-frequency ionosphere-free pseudo-range from the B1C pilot component and the B2a pilot component ($PR_{B1Cp-B2ap}$) shall be computed as follows:

$$PR_{B1Cp-B2ap} = \frac{PR_{B2ap} - k_{12} \cdot PR_{B1Cp}}{1 - k_{12}} - \frac{C \cdot (T_{GDB2ap} - k_{12} \cdot T_{GDB1Cp})}{1 - k_{12}}$$

The dual-frequency pseudo-range from the B1C pilot component and the B2a data component ($PR_{B1Cp-B2ad}$) shall be computed as follows:

$$PR_{B1Cp-B2ad} = \frac{PR_{B2ad} - k_{12} \cdot PR_{B1Cp}}{1 - k_{12}} - \frac{C \cdot (T_{GDB2ap} + ISC_{B2ad} - k_{12} \cdot T_{GDB1Cp})}{1 - k_{12}}$$

The dual-frequency pseudo-range from the B1C data component and the B2a pilot component ($PR_{B1Cd-B2ap}$) shall be computed as follows:

$$PR_{B1Cd-B2ap} = \frac{PR_{B2ap} - k_{12} \cdot PR_{B1Cd}}{1 - k_{12}} - \frac{C \cdot (T_{GDB2ap} - k_{12} \cdot T_{GDB1Cp} - k_{12} \cdot ISC_{B1Cd})}{1 - k_{12}}$$

The dual-frequency pseudo-range from the B1C data component and the B2a data component ($PR_{B1Cd-B2ad}$) shall be computed as follows:

$$PR_{B1Cd-B2ad} = \frac{PR_{B2ad} - k_{12} \cdot PR_{B1Cd}}{1 - k_{12}} - \frac{C \cdot (T_{GDB2ap} + ISC_{B2ad} - k_{12} \cdot T_{GDB1Cp} - k_{12} \cdot ISC_{B1Cd})}{1 - k_{12}}$$

where $K_{12} = \left(\frac{1575.42}{1176.45}\right)^2$, is the factor associated with frequency;

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 93

PR_{B1Cp} is the measured pseudo-range of the B1C pilot component (corrected by the clock correction but not corrected by T_{GDB1Cp});

PR_{B1Cd} is the measured pseudo-range of the B1C data component (corrected by the clock correction but not corrected by T_{GDB1Cp} and ISC_{B1Cd});

PR_{B2ap} is the measured pseudo-range of the B2a pilot component (corrected by the clock correction but not corrected by T_{GDB2ap});

PR_{B2ad} is the measured pseudo-range of the B2a data component (corrected by the clock correction but not corrected by T_{GDB2ap} and ISC_{B2ad});

T_{GDB1Cp} is the group delay differential of the B1C pilot component;

T_{GDB2ap} is the group delay differential of the B2a pilot component;

ISC_{B1Cd} is the group delay differential between the B1C data component and the B1C pilot component;

ISC_{B2ad} is the group delay differential between the B2a data component and the B2a pilot component;

$c = 2.99792458 \times 10^8$ m/s is the speed of light.

Note 1.— Additional information concerning B1C ionospheric delay model parameters is given in BDS OS B1C ICD, section 7.8.

Note 2.— Additional information concerning B2a ionospheric delay model parameters is given in BDS OS B2a ICD, section 7.8.

3.1.4.2.5 SISA calculation for B1C and B2a.

The signal-in-space accuracy (SISA) for integrity use shall be calculated as:

$$SISA = \sqrt{(SISA_{oe} \times \sin 14^\circ)^2 + SISA_{oe}^2}$$

where

$SISA_{oe}$ is the upper bound value corresponding to the $SISA_{oe}$ index “N” as broadcast in B-CNAV1 Subframe 3 for B1C and in B-CNAV2 message Types 34 and 40 for B2a, respectively (defined in 3.1.4.1.3.2.8) as shown in Table B-54.

$SISA_{oc}$ shall be calculated with the following equations (in metres):

$$SISA_{oc} = SISA_{ocb} + SISA_{oc1}(t - t_{op}), \text{ for } t - t_{op} \leq 93600s$$

$$SISA_{oc} = SISA_{ocb} + SISA_{oc1}(t - t_{op}) + SISA_{oc2}(t - t_{op} - 93600)^2, \text{ for } t - t_{op} > 93600s$$

where

$SISA_{ocb}$ is the upper bound value corresponding to the $SISA_{ocb}$ index “N” as broadcast in B-CNAV1 Subframe 3 for B1C and in B-CNAV2 message Types 34 and 40 for B2a, respectively (defined in 3.1.4.1.8) as shown in Table B-55;

$SISA_{oc1}$ is the satellite clock drift accuracy in metres per second derived from $SISAI_{oc1}$ (defined in 3.1.4.1.3.2.8) as follows:

$$SISA_{oc1} = 2^{-(SISAI_{oc1} + 14)}$$

$SISA_{oc2}$ is the satellite clock drift rate accuracy in metres per square second derived from $SISAI_{oc2}$ (defined in 3.1.4.1.3.2.8) as follows:

$$SISA_{oc2} = 2^{-(SISAI_{oc2} + 28)}$$

where

t is the BDS system time in second;

t_{op} is the time of week for data prediction in second broadcast in B-CNAV1 subframe 3 for B1C and in B CNAV2 message Types 34 and 40 for B2a, respectively.

3.1.4.3 Aircraft Elements

3.1.4.3.1 BDS receiver

3.1.4.3.1.1 Satellite tracking. The receiver shall provide the capability to continuously track a minimum of four BDS satellites and generate a position solution based upon those measurements.

3.1.4.3.1.2 Doppler shift. The receiver shall be able to compensate for dynamic Doppler shift effects on nominal BDS OS signal carrier phase and ranging code measurements. The receiver shall compensate for the Doppler shift that is unique to the anticipated application.

3.1.4.3.1.3 Resistance to interference. The receiver shall meet the requirements for resistance to interference as specified in section 3.7.

3.1.4.3.1.4 Application of clock and ephemeris data. The receiver shall ensure that it is using the correct ephemeris and clock data before providing any position solution. For B1I, the receiver shall monitor the parameters t_{oc} and t_{oe} to update clock and ephemeris data based upon the detected change in these parameters. For B1C and B2a, the receiver shall monitor the parameters IODC and IODE to update clock and ephemeris data based upon the detected change in these parameters.

3.1.4.4 Time

The time reference for BDS shall be the BeiDou Navigation Satellite System Time (BDT). BDT shall adopt the International System of Units (SI) seconds, and shall accumulate continuously without leap seconds. The start epoch of BDT shall be 00:00:00 on 1 January 2006 of Coordinated Universal Time (UTC). BDT shall connect with UTC via UTC (NTSC), and the deviation of BDT to UTC shall be maintained within 50 nanoseconds (Modulo 1 second). The leap seconds shall be broadcast in the navigation (NAV) message.

3.1.4.5 Coordinate System

3.1.4.5.1 *BeiDou Coordinate System*. The BDS broadcast ephemeris shall describe the position of the transmitting antenna phase centre of a given satellite in the BeiDou Coordinate System (BDCS).

3.1.4.5.2 The difference between the latest physical realization of ITRF and BDCS shall not exceed 3 cm (95 per cent).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 95

Note 1.— WGS-84 and BDS terrestrial reference frame BDCS are both realizations of ITRF. The difference between BDCS and WGS-84 used in GPS is considered insignificant for aviation.

Note 2.— Additional information on the BDCS is in Attachment D, section 4.1.4.9.

3.2 (Reserved)

3.3 Use of multiple core satellite constellations

3.3.1 Aircraft Elements

3.3.1.1 *Multi-constellation GNSS receiver.* The multi-constellation GNSS receiver shall process signals from two or more core satellite constellations in accordance with the requirements specified in 3.1.1.3.1, GPS receiver,

3.1.2.3.1, GLONASS (GNSS) receiver, 3.1.3.3.1, Galileo receiver and 3.1.4.3.1, BDS receiver.

3.3.1.1.1 *Resistance to interference.* The multi-constellation GNSS receiver shall meet the individual requirements for the core satellite constellations processed as specified in 3.7.

3.3.1.2 *Antenna(e).* Core satellite constellation signals shall be received through one or more antennae.

Note.— Performance characteristics of GNSS receiver antennae are defined in 3.8.

3.3.1.3 Position information provided by a multi-constellation GNSS receiver shall be expressed in WGS-84 earth coordinates.

3.3.1.4 When combining measurements from core satellite constellations, the difference among each core satellite constellation reference time shall be taken into account.

3.3.1.4.1 Multi-constellation GNSS receivers shall solve for the time offset between the core constellations as an additional unknown parameter in the navigation solution and not only rely on the time offset broadcast in the navigation messages. 3.4 Aircraft-based augmentation system (ABAS)

Note.— Guidance on ABAS is given in Attachment D, section 5.

3.4 Aircraft-based augmentation system (ABAS)

Note.— Guidance on ABAS and associated signal processing is given in Attachment D, section 5.

3.5 Satellite-based augmentation system (SBAS)

3.5.1 General

Note – Geodetic parameters in this section are defined in WGS-84.

3.5.1.1 *SBAS system and service description.* SBAS shall consist of a non-aircraft subsystem and an aircraft subsystem. The SBAS non-aircraft subsystem shall provide data and corrections for the GNSS ranging signals over one or two GNSS frequencies broadcast from a satellite to the aircraft subsystem. The SBAS non-aircraft subsystem shall broadcast on the L1 frequency to support the L1 SBAS service and/or on the L5 frequency to support the DFMC SBAS service.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 96

Note.— The SBAS non-aircraft subsystem may provide a single-frequency ranging signal on the SBAS L1 frequency or a dual-frequency ranging signal as a combination of the signals transmitted on the SBAS L1 and SBAS L5 frequencies.

3.5.1.2 SBAS pseudo-range definition.

3.5.1.2.1 Carrier smoothing. Carrier smoothing shall be defined by the following filter:

$$P_{CSC,k} = \alpha P_{meas} + (1 - \alpha) P_{proj}$$

$$P_{proj} = (P_{CSC,k-1} + \Delta_{carrier_range})$$

where

- $P_{CSC,k}$ = the carrier smoothed code pseudo-range at time k;
- $P_{CSC,k-1}$ = the previous carrier smoothed code pseudo-range at time k-1;
- P_{meas} = the measured pseudo-range as defined below;
- $\Delta_{carrier_range}$ = the change in carrier range as defined below, and
- α = the filter weighting function equal to the sample interval divided by the smoothing time constant.

$$P_{meas} = \begin{cases} \text{single-frequency:} & P_{1,k} \\ \text{ionosphere-free:} & \frac{\gamma_{12}(P_{1,k}) - (P_{2,k})}{(\gamma_{12} - 1)} \end{cases}$$

where

- $P_{n,k}$ = the raw pseudo-range of frequency n at time k; and
- γ_{12} = the square of the ratio of frequency 1 to frequency 2;

$$\Delta_{carrier_range} = \begin{cases} \text{single-frequency:} & (\varphi_{1,k} - \varphi_{1,k-1}) \\ \text{ionosphere-free:} & \frac{\gamma_{12}(\varphi_{1,k} - \varphi_{1,k-1}) - (\varphi_{2,k} - \varphi_{2,k-1})}{(\gamma_{12} - 1)} \end{cases}$$

where

- $\varphi_{n,k}$ = the accumulated carrier in metres for frequency n at time k; and
- $\varphi_{n,k-1}$ = the accumulated carrier in metres for frequency n at time k-1.

3.5.1.2.2 Corrected pseudo-range. The corrected pseudo-range for a given satellite i at time t is:

$$PR_{t,corrected} = P_{CSC,i} + TC_i + b_i$$

where

- $P_{CSC,i}$ = the smoothed pseudo-range (defined in 3.5.1.1);
- TC_i = the tropospheric correction (defined in 3.5.5.3 for SBAS); and
- b_i = the clock correction.

3.5.2 SBAS L1 RF Characteristics

3.5.2.1 Carrier frequency stability. The short-term stability of the carrier frequency (square root of the Allan Variance) at the output of the satellite transmit antenna shall be better than 5×10^{-11} over 1 to 10 seconds.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 97

3.5.2.2 Carrier phase noise. The phase noise spectral density of the unmodulated carrier shall be such that a phase locked loop of 10 Hz one-sided noise bandwidth is able to track the carrier to an accuracy of 0.1 radian (1 sigma).

3.5.2.3 Spurious emissions. Spurious emissions shall be at least 40 dB below the unmodulated carrier power over all frequencies.

3.5.2.4 Code/carrier frequency coherence. The short-term (less than 10 seconds) fractional frequency difference between the code phase rate and the carrier frequency shall be less than 5×10^{-11} (standard deviation). Over the long term (less than 100 seconds), the difference between the change in the broadcast code phase, converted to carrier cycles by multiplying the number of code chips by 1 540, and the change in the broadcast carrier phase, in cycles, shall be within one carrier cycle (standard deviation).

Note.— This applies to the output of the satellite transmit antenna and does not include code/carrier divergence due to ionospheric refraction in the downlink propagation path.

3.5.2.5 Correlation loss. The loss in the recovered signal power due to imperfections in the signal modulation and waveform distortion shall not exceed 1 dB.

Note.— The loss in signal power is the difference between the broadcast power in a 2.046 MHz bandwidth and the signal power recovered by a noise-free, loss-free receiver with 1-chip correlator spacing and a 2.046 MHz bandwidth.

3.5.2.6 Maximum code phase deviation. The maximum uncorrected code phase of the broadcast L1 signal shall not deviate from the equivalent SBAS network time (SNT) for L1 SBAS by more than $\pm 2^{-20}$ seconds.

3.5.2.7 Code/data coherence. Each 2-millisecond symbol shall be synchronous with every other code epoch.

3.5.2.8 Message synchronization. The leading edge of the first symbol that depends on the first bit of the current message shall be broadcast from the SBAS satellite synchronous with a 1-second epoch of SNT for L1 SBAS.

3.5.2.9 Convolutional encoding. A 250-bit-per-second data stream shall be encoded at a rate of 2 symbols per bit using a convolutional code with a constraint length of 7 to yield 500 symbols per second. The convolutional encoder logic arrangement shall be as illustrated in Figure B-11 with the G3 output selected for the first half of each 4-millisecond data bit period.

3.5.2.10 Pseudo-random noise (PRN) codes. Each PRN code shall be a 1 023-bit Gold code which is itself the Modulo-2 addition of two 1 023-bit linear patterns, G1 and G2_i. The G2_i sequence shall be formed by delaying the G2 sequence by the associated integer number of chips as illustrated in Table B-23. Each of the G1 and G2 sequences shall be defined as the output of stage 10 of a 10-stage shift register, where the input to the shift register is the Modulo-2 addition of the following stages of the shift register:

1. G1: stages 3 and 10; and
2. G2: stages 2, 3, 6, 8, 9 and 10.

The initial state for the G1 and G2 shift registers shall be “1111111111”

3.5.3 Data Structure on SBAS L1 signal

Note.— Messages broadcast on SBAS L1 signal are independent of those broadcast on SBAS L5 signal. Information broadcast on SBAS L1 signal is used only for the L1 SBAS service using GPS L1 C/A and GLONASS L1OF (FDMA signal).

3.5.3.1 Format summary. All messages shall consist of a message type identifier, a preamble, a data field and a cyclic redundancy check as illustrated in Figure B-25.

3.5.3.2 Preamble. For L1, the preamble shall consist of the sequence of bits “01010011 10011010 11000110”, distributed over three successive blocks. The start of every other 24-bit preamble shall be synchronous with a 6-second GPS sub-frame epoch.

3.5.3.3 Message type identifier. The L1 message type identifier shall be a 6-bit value identifying the message type (Types 0 to 63) as defined in Table B-62. The message type identifier shall be transmitted MSB first.

3.5.3.4 Data field. The L1 data field shall be 212 bits as defined in 3.5.6. Each data field parameter shall be transmitted MSB first.

3.5.3.5 Cyclic redundancy check (CRC). The SBAS message CRC code L1 shall be calculated in accordance with 3.9.

3.5.3.5.1 The length of the CRC code shall be $k = 24$ bits.

3.5.3.5.2 The CRC generator polynomial shall be:

$$G(x) = x^{24} + x^{23} + x^{18} + x^{17} + x^{14} + x^{11} + x^{10} + x^7 + x^6 + x^5 + x^4 + x^3 + x + 1$$

Table B-62. L1 broadcast message types

<i>L1 Message type</i>	<i>Contents</i>
0	“Do Not Use” (SBAS test mode) – content applies to L1 SBAS service only
1	PRN mask
2 to 5	Fast corrections
6	Integrity information
7	Fast correction degradation factor
8	Spare
9	GEO ranging function parameters
10	Degradation parameters
11	Spare
12	SBAS network time/UTC offset parameters
13 to 16	Spare
17	GEO satellite almanacs
18	Ionospheric grid point masks
19 to 23	Spare
24	Mixed fast/long-term satellite error corrections
25	Long-term satellite error corrections
26	Ionospheric delay corrections
27	SBAS service message
28	Clock-ephemeris covariance matrix
29 to 61	Spare
62	Reserved – content applies to L1 SBAS service only
63	Null message – content applies to L1 SBAS service only

Note.— L1 messages (Table B-24) are for use with L1 SBAS service and L5 messages (Table B-90) are for use with DFMC SBAS service. Types 0, 62 and 63 messages are used independently by both L1 SBAS and DFMC SBAS services and their contents only apply to their service.

3.5.3.5.3 The CRC information field, $M(x)$, shall be:

$$M(x) = \sum_{i=1}^{226} m_i x^{226-i} = m_1 x^{225} + m_2 x^{224} + \dots + m_{226} x^0$$

3.5.3.5.4 M(x) shall be formed from the 8-bit SBAS message preamble, 6-bit message type identifier, and 212-bit data field. Bits shall be arranged in the order transmitted from the SBAS satellite, such that m_1 corresponds to the first transmitted bit of the preamble, and m_{226} corresponds to bit 212 of the data field.

3.5.3.5.5 The CRC code r-bits shall be ordered such that r_1 is the first bit transmitted and r_{24} is the last bit transmitted.

3.5.4 L1 SBAS Data Content

3.5.4.1 PRN mask parameters. PRN mask parameters shall be as follows:

PRN code number: a number that uniquely identifies the satellite PRN code and related assignments as shown in Table B-63.

PRN mask: 210 PRN mask values that correspond to satellite PRN code numbers. The mask shall set up to 51 of the 210 PRN mask values.

Note.— The first transmitted bit of the PRN mask corresponds to PRN code number 1.

Table B-63. PRN code number assignments

<i>PRN code number</i>	<i>Assignment</i>
1 – 37	GPS
38 – 61	GLONASS slot number plus 37
62 – 119	Spare
120 – 158	SBAS
159 – 210	Spare

PRN mask value: a bit in the PRN mask indicating whether data are provided for the associated satellite PRN code number (1 to 210).

Coding: 0 = data not provided
1 = data provided

PRN mask number: the sequence number (1 to 51) of the mask values set in the PRN mask.

Note.— The PRN mask number is “1” for the lowest satellite PRN number for which the PRN mask value is “1”.

Issue of data — PRN (IODP): an indicator that associates the correction data with a PRN mask.

Note.— Parameters are broadcast in the following messages:

- a) PRN mask (consisting of 210 PRN mask values) in Type 1 message;*
- b) PRN mask number in Type 24, 25 and 28 messages;*
- c) PRN code number in Type 17 message; and*
- d) IODP in Type 1 to 5, 7, 24, 25 and 28 messages.*

3.5.4.2 Geostationary orbit (GEO) ranging function parameters. GEO ranging function parameters shall be as follows:

$t_{0,GEO}$: the reference time for the GEO ranging function data, expressed as the time after midnight of the current day.

$[X_G Y_G Z_G]$: the position of the GEO at time $t_{0,GEO}$.

$[\dot{X}_G \dot{Y}_G \dot{Z}_G]$: the velocity of the GEO at time $t_{0,GEO}$.

$[\ddot{X}_G \ddot{Y}_G \ddot{Z}_G]$: the acceleration of the GEO at time $t_{0,GEO}$.

a_{Gf0} : the time offset of the GEO clock with respect to SNT for L1 SBA, defined at $t_{0,GEO}$.

a_{Gf1} : the drift rate of the GEO clock with respect to SNT for L1 SBA.

User range accuracy (URA): an indicator of the root-mean-square ranging error, excluding atmospheric effects, as described in Table B-64.

Note.— All parameters are broadcast in Type 9 message.

Table B-64. User range accuracy

URA	Accuracy (rms)
0	2 m
1	2.8 m
2	4 m
3	5.7 m
4	8 m
5	11.3 m
6	16 m
7	32 m
8	64 m
9	128 m
10	256 m
11	512 m
12	1 024 m
13	2 048 m
14	4 096 m
15	“Do Not Use”

Note.— URA values 0 to 14 are not used in the protocols for data application (3.5.5). Airborne receivers will not use the GEO ranging function if URA indicates “Do Not Use” (3.5.8.3).

3.5.4.3 GEO almanac parameters. GEO almanac parameters shall be as follows:

PRN code number: see 3.5.4.1.

Health and status: an indication of the functions provided by the SBAS. The service provider identifiers are shown in Table B-65

Coding:	Bit 0 (LSB)	Ranging	On (0)	Off (1)
	Bit 1	Precision corrections	On (0)	Off (1)
	Bit 2	Satellite status and basic corrections	On (0)	Off (1)
	Bits 3	Spare		
	Bits 4 to 7	Service provider identifier		

$[X_{G,A} \dot{Y}_{G,A} Z_{G,A}]$: the position of the GEO at time $t_{almanac}$.

$[\dot{X}_{G,A} \dot{Y}_{G,A} \dot{Z}_{G,A}]$: the velocity of the GEO at time $t_{almanac}$.

$t_{almanac}$: the reference time for the GEO almanac data, expressed as the time after midnight of the current day.

Note - All parameters are broadcast in Type 17 message.

3.5.4.4 Satellite Correction Broadcast Parameter

3.5.4.4.1 Long-term correction parameters shall be as follows:

Issue of data (IOD_i): an indicator that associates the long-term corrections for the i^{th} satellite with the ephemeris data broadcast by that satellite.

Note 1 - For GPS, the IOD_i matches the IODE and 8 LSBs of the IODC (3.1.1.3.1.4 and 3.1.1.3.2.2).

Note 2 - For GLONASS, the IOD_i indicates a period of time that GLONASS data are to be used with SBAS data. It consists of two fields as shown in Table B-66.

δx_i : for satellite i , the ephemeris correction for the x axis.

δy_i : for satellite i , the ephemeris correction for the y axis.

δz_i : for satellite i , the ephemeris correction for the z axis.

$\delta a_{i,f0}$: for satellite i , the ephemeris time correction.

$\delta x'_i$: for satellite i , ephemeris velocity correction for x axis.

$\delta y'_i$: for satellite i , ephemeris velocity correction for y axis.

$\delta z'_i$: for satellite i , ephemeris velocity correction for z axis.

$\delta a_{i,f1}$: for satellite i , rate of change of the ephemeris time correction.

t_i, LT : the time of applicability of the parameters δx_i , δy_i , δz_i , $\delta a_{i,f0}$, $\delta x'_i$, $\delta y'_i$, $\delta z'_i$ and $\delta a_{i,f1}$, expressed in seconds after midnight of the current day.

Velocity code: an indicator of the message format broadcast (Table B-86 and Table B-87).

Coding: 0 = $\delta x'_i$, $\delta y'_i$, $\delta z'_i$ and $\delta a_{i,f1}$ are not broadcast.

1 = $\delta x'_i$, $\delta y'_i$, $\delta z'_i$ and $\delta a_{i,f1}$ are broadcast.

Note - All parameters are broadcast in Type 24 and 25 messages.

Table B-65. SBAS service provider identifiers

<i>Identifier</i>	<i>Service provider</i>
0	WAAS
1	EGNOS
2	MSAS
3	GAGAN
4	SDCM
5	BDSBAS
6	KASS
7	ANGA
8	SouthPAN
9 to 13	Reserved for SBAS
14, 15	Reserved
16 to 31	Reserved for SBAS provider supporting DFMC SBAS only

Note 1.— A service provider ID of 14 is used for GBAS and is not applicable to SBAS.

Note 2.— Service provider IDs of 16 to 31 cannot be coded in the L1 SBAS message.

Table B-66. IOD_i for GLONASS satellites

MSB	LSB
Validity interval (5 bits)	Latency time (3 bits)

3.5.4.4.2 Fast correction parameters shall be as follows:

Fast correction (FC_i): for satellite *i*, the pseudo-range correction for rapidly varying errors, other than tropospheric or ionospheric errors, to be added to the pseudo-range after application of the long-term correction.

Note - The user receiver applies separate tropospheric corrections (3.5.8.4.2 and 3.5.8.4.3).

Fast correction type identifier: an indicator (0, 1, 2, 3) of whether the Type 24 message contains the fast correction and integrity data associated with the PRN mask numbers from Type 2, Type 3, Type 4 or Type 5 messages, respectively.

Issue of data-fast correction (IODF_j): an indicator that associates UDREI_s with fast corrections. The index *j* shall denote the message type (*j* = 2 to 5) to which IODF_j applies (the fast correction type identifier +2).

Note.— The fast correction type identifier is broadcast in Type 24 messages. The FC_i are broadcast in Type 2 to 5, and Type 24 messages. The IODF_j are broadcast in Type 2 to 6, and Type 24 messages.

3.5.4.5 Fast and long-term correction integrity parameters. Fast and long-term correction integrity parameters shall be as follows:

UDREI_i: an indicator that defines the $\sigma_{i,UDRE}^2$ for satellite i as described in Table B-67.

Model variance of residual clock and ephemeris errors ($\sigma_{i,UDRE}^2$): the variance of a normal distribution associated with the user differential range errors for satellite i after application of fast and long-term corrections, excluding atmospheric effects and used in horizontal protection level/vertical protection level computations (3.5.5.6).

Note - All parameters are broadcast in Type 2 to 6, and Type 24 messages.

3.5.4.6 Ionospheric correction parameters. Ionospheric correction parameters shall be as follows:

IGP mask: a set of 11 ionospheric grid point (IGP) band masks defined in Table B-68.

IGP band mask: a set of IGP mask values which correspond to all IGP locations in one of the 11 IGP bands defined in Table B-30.

IGP mask value: a bit indicating whether data are provided within that IGP band for the associated IGP.

Coding: 0 = data are not provided

1 = data are provided

Number of IGP bands: the number of IGP band masks being broadcast.

IGP band identifier: the number identifying the ionospheric band as defined in Table B-68.

Table B-67. Evaluation of UDREI_i

<i>UDREI_i</i>	$\sigma_{i,UDRE}^2$
0	0.0520 m ²
1	0.0924 m ²
2	0.1444 m ²

14	“Not Monitored”
15	“Do Not Use”

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 106

IGP block identifier: the identifier of the IGP block. The IGP blocks are defined by dividing into groups of 15 IGPs the sequence of IGPs within an IGP band mask which have IGP mask values of “1”. The IGP blocks are numbered in an order of IGP mask value transmission, starting with “0”.

Validity interval (V): the time interval for which the GLONASS ephemeris data are applicable (coded with an offset of 30 s) as described in Table B-69.

Latency time (L): the time interval between the time the last GLONASS ephemeris has been received by the ground segment and the time of transmission of the first bit of the long-term correction message at the GEO(t_{lc}) as described in Table B-30.

IODI_k: an indication of when the kth IGP band mask changes.

IGP vertical delay estimate: an estimate of the delay induced for a signal at 1 575.42 MHz if it traversed the ionosphere vertically at the IGP.

Coding: The bit pattern “11111111” indicates “Do Not Use”.

GIVEI_i: an indicator that defines the $\sigma^2_{i,GIVE}$ as described in Table B-71.

Model variance of residual ionospheric errors ($\sigma^2_{i,GIVE}$): the variance of a normal distribution associated with the residual ionospheric vertical error at the IGP for an L1 signal.

Note - All parameters are broadcast in Type 18 and Type 26 messages.

Table B-68. IGP locations and band numbers

IGP location		Transmission order in IGP band mask
Band 0

3.5.4.7 Degradation parameters. Degradation parameters, whenever used, shall be as follows:

Fast correction degradation factor indicator (ai_i): an indicator of the fast correction degradation factor (a_i) for the i^{th} satellite as described in Table B-72.

Note - The ai_i is also used to define the time-out interval for fast corrections, as described in 3.5.8.1.2.

System latency time (t_{lat}): the time interval between the origin of the fast correction degradation and the user differential range estimate indicator (UDREI) reference time.

B_{rrc} : a parameter that bounds the noise and round-off errors when computing the range rate correction degradation as in 3.5.5.6.2.2.

C_{ltc_lsb} : the maximum round-off error due to the resolution of the orbit and clock information.

C_{ltc_vl} : the velocity error bound on the maximum range rate difference of missed messages due to clock and orbit rate differences.

I_{ltc_vl} : the update interval for long-term corrections if velocity code = 1 (3.5.4.4.1).

C_{ltc_v0} : a parameter that bounds the difference between two consecutive long-term corrections for satellites with a velocity code = 0.

I_{ltc_v0} : the minimum update interval for long-term messages if velocity code = 0 (3.5.4.4.1).

C_{GEO_lsb} : the maximum round-off error due to the resolution of the orbit and clock information.

C_{GEO_vl} : the velocity error bound on the maximum range rate difference of missed messages due to clock and orbit rate differences.

I_{GEO} : the update interval for GEO ranging function messages.

Table B-72. Fast correction degradation factor

<i>Fast correction degradation factor indicator (a_i)</i>	<i>Fast correction degradation factor (a_i)</i>
0	0.0 mm/s ²
1	0.05 mm/s ²
2	0.09 mm/s ²
3	0.12 mm/s ²
4	0.15 mm/s ²
5	0.20 mm/s ²
6	0.30 mm/s ²
7	0.45 mm/s ²
8	0.60 mm/s ²
9	0.90 mm/s ²
10	1.50 mm/s ²
11	2.10 mm/s ²
12	2.70 mm/s ²
13	3.30 mm/s ²
14	4.60 mm/s ²
15	5.80 mm/s ²

C_{er} : the bound on the residual error associated with using data beyond the precision approach/approach with vertical guidance time-out.

C_{iono_step} : the bound on the difference between successive ionospheric grid delay values.

I_{iono} : the minimum update interval for ionospheric correction messages.

C_{iono_ramp} : the rate of change of the ionospheric corrections.

RSS_{UDRE} : the root-sum-square flag for fast and long-term correction residuals.

Coding: 0 = correction residuals are linearly summed

1 = correction residuals are root-sum-squared

RSS_{iono} : the root-sum-square flag for ionospheric residuals.

Coding: 0 = correction residuals are linearly summed

1 = correction residuals are root-sum-squared

$C_{covariance}$: the term which is used to compensate for quantization effects when using the Type 28 message.

Note 1 - The parameters a_i and t_{lat} are broadcast in Type 7 message. All other parameters are broadcast in Type 10 message.

Note 2 - If message Type 28 is not broadcast, $C_{covariance}$ is not applicable.

3.5.4.8 Time parameters. Time parameters, whenever used, shall be as follows:

UTC standard identifier: an indication of the UTC reference source as defined in Table B-73.

GPS time-of-week count: the number of seconds that have passed since the transition from the previous GPS week (similar to the GPS parameter in 3.1.1.2.6.1 but with a 1-second resolution).

Table B-73. UTC standard identifier

<i>UTC standard identifier</i>	<i>UTC standard</i>
0	UTC as operated by the National Institute of Information and Communications Technology, Tokyo, Japan
1	UTC as operated by the U.S. National Institute of Standards and Technology
2	UTC as operated by the U.S. Naval Observatory
3	UTC as operated by the International Bureau of Weights and Measures
4	Reserved for UTC as operated by a European laboratory
5	UTC as operated by the National Time Service Center, Chinese Academy of Sciences
6	Reserved
7	UTC not provided
8 to 15	Reserved for DFMC SBAS only

Note.— UTC standard identifiers of 8 to 15 cannot be coded in the L1 SBAS message.

GPS week number (week count): see 3.1.1.2.6.2.

GLONASS indicator : a flag indicating if GLONASS time parameters are provided.

Coding: 0 = GLONASS time parameters are not provided

1 = GLONASS time parameters are provided

GLONASS time offset L1 ($\delta a_{i, \text{GLONASS}}$): A parameter broadcast on L1 that represents the stable part of the offset between the 1 GLONASS time and the L1 SBAS network time.

Note.— If L1 SBAS does not support GLONASS, $\delta a_{i, \text{GLONASS}}$ is not applicable.

UTC parameters: $A_{1\text{SNT}}$, $A_{0\text{SNT}}$, t_{0t} , WN_t , t_{LS} , WN_{LSF} , DN and t_{LSF} are as described in 3.1.1.3.3.6, with the exception that the SBAS parameters relate SNT to UTC time, rather than GPS time.

Note.— All parameters are broadcast in Type 12 message.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 113

3.5.4.9 Service region parameters. Service region parameters shall be as follows:

Issue of data, service (IODS): an indication of a change of the service provided in the region.

Number of service messages: the number of different Type 27 SBAS service messages being broadcast. (Value is coded with an offset of 1.)

Service message number: a sequential number identifying the message within the currently broadcast set of Type 27 messages (from 1 to number of service messages, coded with an offset of 1).

Number of regions: the number of service regions for which coordinates are broadcast in the message.

Priority code: an indication of a message precedence if two messages define overlapping regions. The message with a higher value of priority code takes precedence. If priority codes are equal, the message with the lower δ UDRE takes precedence.

δ UDRE indicator-inside: an indication of regional UDRE degradation factor (δ UDRE) applicable at locations inside any region defined in the message, in accordance with Table B-36.

δ UDRE indicator-outside: an indication of regional UDRE degradation factor (δ UDRE) applicable at locations outside all regions defined in all current Type 27 messages, in accordance with Table B-36.

Coordinate latitude: the latitude of one corner of a region.

Coordinate longitude: the longitude of one corner of a region.

Region shape: an indication of whether a region is a triangle or quadrangle.

Coding: 0 = triangle
1 = quadrangle

Note 1 - Coordinate 3 has Coordinate 1 latitude and Coordinate 2 longitude. If region is a quadrangle, Coordinate 4 has Coordinate 2 latitude and Coordinate 1 longitude. Region boundary is formed by joining coordinates in the sequence 1-2-3-1 (triangle) or 1-3-2-4-1 (quadrangle). Boundary segments have either constant latitude, constant longitude, or constant slope in degrees of latitude per degree of longitude. The change in latitude or longitude along any boundary segment between two coordinates is less than ± 180 degrees.

Note 2 - All parameters are broadcast in Type 27 message.

Table B-74. δ UDRE indicator evaluation

3.5.4.10 Clock-ephemeris covariance matrix parameters. Clock-ephemeris covariance matrix parameters shall be as follows:

PRN mask number: see 3.5.4.1.

Scale exponent: A term to compute the scale factor used to code the Cholesky factorization elements.

Cholesky factorization elements ($E_{i,j}$): Elements of an upper triangle matrix which compresses the information in the clock and ephemeris covariance matrix. These elements are used to compute the user differential range estimate (UDRE) degradation factor (δ UDRE) as a function of user position.

3.5.5 Definitions of Protocols for L1 SBAS data Application

Note.— This section provides definitions of parameters used by the non-aircraft or aircraft elements that are not transmitted. These parameters, necessary to ensure interoperability of SBAS, are used to determine the navigation solution and its integrity (protection levels).

3.5.5.1 GEO Position and Clock

3.5.5.1.1 GEO position estimate. The estimated position of a GEO at any time t_k is:

$$\begin{bmatrix} \hat{X}_G \\ \hat{Y}_G \\ \hat{Z}_G \end{bmatrix} = \begin{bmatrix} X_G \\ Y_G \\ Z_G \end{bmatrix} + \begin{bmatrix} \dot{X}_G \\ \dot{Y}_G \\ \dot{Z}_G \end{bmatrix} (t-t_{0,GEO}) + \frac{1}{2} \begin{bmatrix} \ddot{X}_G \\ \ddot{Y}_G \\ \ddot{Z}_G \end{bmatrix} (t-t_{0,GEO})^2$$

3.5.5.1.2 GEO clock correction. The clock correction for a SBAS GEO satellite i is applied in accordance with the following equation:

$$t = t_G - \Delta t_G$$

Where

t = SBAS network time;

t_G = GEO code phase time at transmission of message; and

Δt_G = GEO code phase offset.

3.5.5.1.2.1 GEO code phase offset (Δt_G) at any time t is:

$$\Delta t_G = a_{Gf0} + a_{Gf1} (t - t_{0,GEO})$$

where $(t - t_{0,GEO})$ is corrected for end - of - day crossover.

3.5.5.2 Long Term Correction

3.5.5.2.1 GPS clock correction. The clock correction for a GPS satellite i is applied in accordance with the following equation.

$$t = t_{SV,i} - [(\Delta t_{SV,i})_{L1} + \delta \Delta t_{SV,i}]$$

Where

t = SBAS network time;

$t_{SV,i}$ = the GPS satellite time at transmission of message;

$(\Delta t_{SV,i})_{L1}$ = the satellite PRN code phase offset as defined in 3.1.2.2; and

$\delta \Delta t_{SV,i}$ = the code phase offset correction.

3.5.5.2.1.1 The code phase offset correction ($\delta \Delta t_{SV,i}$) for a GPS or SBAS satellite i at any time of day t_k is:

$$\delta \Delta t_{SV,i} = \delta a_{i,f0} + a_{i,f1} (t_k - t_{i,LT})$$

3.5.5.2.2 GLONASS clock correction. The clock correction for a GLONASS satellite i is applied in accordance with the following equation

$$t = t_{SV,i} + \tau_n(t_b) - \gamma_n(t_b) (t_{SV,i} - t_b) - \delta \Delta t_{SV,i}$$

Where

t = SBAS network

$t_{SV,i}$ = the GLONASS satellite time at transmission of message

$t_b, \tau_n(t_b), \gamma_n(t_b)$ = the GLONASS time parameters as defined in 3.2.2.2

$\delta \Delta t_{SV,i}$ = the code phase offset correction

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 116

The code phase offset correction $\delta\Delta t_{SV,i}$ for a GLONASS satellite i is:

$$\delta\Delta t_{SV,i} = \delta a_{i,f0} + \delta a_{i,f1}(t - t_{i,LT}) + \delta a_{i,GLONASS}$$

where $(t - t_{i,LT})$ is corrected for end-of-day crossover. If the velocity code = 0, then $\delta a_{i,f1} = 0$.

3.5.5.2.3 Satellite position correction. The SBAS-corrected vector for a core satellite constellation(s) or SBAS satellite i at time t is:

$$\begin{bmatrix} X_i \\ Y_i \\ Z_i \end{bmatrix}_{\text{corrected}} = \begin{bmatrix} X_i \\ Y_i \\ Z_i \end{bmatrix} + \begin{bmatrix} \delta X_i \\ \delta Y_i \\ \delta Z_i \end{bmatrix} + \begin{bmatrix} \delta \dot{X}_i \\ \delta \dot{Y}_i \\ \delta \dot{Z}_i \end{bmatrix} (t - t_{i,LT})$$

where

$(t - t_{i,LT})$ is corrected for end-of-day crossover; and

$[X_i \ Y_i \ Z_i]^T$ = the core satellite constellation(s) or SBAS satellite position vector as defined in 3.1.2.3, 3.2.2.3 and 3.5.5.1.1.

If the velocity code = 0, then $[\delta \dot{X}_i \ \delta \dot{Y}_i \ \delta \dot{Z}_i]^T = [0 \ 0 \ 0]^T$.

3.5.5.3 Pseudo-range corrections. The corrected pseudo-range at time t for satellite i is:

$$PR_{i,\text{Corrected}} = PR_i + FC_i + PRC_i (t - t_{i,of}) + IC_i + TC_i$$

where

PR_i = the measured pseudo-range after application of the satellite clock correction;

FC_i = the fast correction;

RRC_i = the range rate correction;

IC_i = the ionospheric correction;

TC_i = the tropospheric correction (negative value representing the troposphere delay); and

$t_{i,of}$

= the time of applicability of the most recent fast corrections, which is the start of the epoch of the SNT second that is coincident with the transmission at the SBAS satellite of the first symbol of the message block.

3.5.5.4 Range rate corrections (RRC). The range rate correction for satellite i is:

$$RRC_i = \begin{cases} \frac{FC_{i,\text{current}} - FC_{i,\text{previous}}}{t_{i,of} - t_{i,of-\text{previous}}}, & \text{if } a_i \neq 0 \\ 0, & a_i = 0 \end{cases}$$

where

$FC_{i,\text{current}}$ = the most recent fast correction;

$FC_{i,\text{previous}}$ = a previous fast correction;

$t_{i,of}$ = the time of applicability of $FC_{i,\text{current}}$;

$t_{i,of-\text{previous}}$ = the time of applicability of $FC_{i,\text{previous}}$; and

a_i = fast correction degradation factor (see Table B-34).

3.5.5.5 Broadcast of Ionospheric Corrections

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 117

3.5.5.5.1 Location of ionospheric pierce point (IPP). The location of an IPP is defined to be the intersection of the line segment from the receiver to the satellite and an ellipsoid with constant height of 350 km above the WGS-84 ellipsoid. This location is defined in WGS-84 latitude (φ_{pp}) and longitude (λ_{pp}).

3.5.5.5.2 Ionospheric corrections. The ionospheric correction for satellite i is:

$$IC_i = -F_{pp} \tau_{vpp}$$

where

$$F_{pp} = \text{obliquity factor} = \left[\frac{(R_e \cos \theta_i)^2}{R_e + h_1} \right]^{-\frac{1}{2}}$$

τ_{vpp} = interpolated vertical ionospheric delay estimate (3.5.5.5.3);

$R_e = 6\,378.1363$ km;

θ_i = elevation angle of satellite i ; and

$h_1 = 350$ km.

Note. — For GLONASS satellites, the ionospheric correction (IC_i) is to be multiplied by the square of the ratio of the GLONASS to the GPS frequencies ($f_{GLONASS}/f_{GPS}$)².

3.5.5.5.3 Interpolated vertical ionospheric delay estimate. When four points are used for interpolation, the interpolated vertical ionospheric delay estimate at latitude φ_{pp} and longitude λ_{pp} is:

$$\tau_{vpp} = \sum_{k=1}^4 W_k \tau_{vk}$$

where

τ_{vk} : the broadcast grid point vertical delay values at the k th corner of the IGP grid, as shown in Figure B-13.

$$W_1 = x_{pp} y_{pp};$$

$$W_2 = (1 - x_{pp}) y_{pp};$$

$$W_3 = (1 - x_{pp})(1 - y_{pp}); \text{ and}$$

$$W_4 = x_{pp}(1 - y_{pp}).$$

3.5.5.5.3.1 For IPPs between N85° and S85°:

$$x_{pp} = \frac{\lambda_{pp} - \lambda_1}{\lambda_2 - \lambda_1}$$

$$y_{pp} = \frac{\varphi_{pp} - \varphi_1}{\varphi_2 - \varphi_1}$$

where

λ_1 = longitude of IGPs west of IPP;

λ_2 = longitude of IGPs east of IPP;

φ_1 = latitude of IGPs south of IPP; and

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 118

φ_2 = latitude of IGPs north of IPP.

Note. — If λ_1 and λ_2 cross 180 degrees of longitude, the calculation of x_{pp} must account for the discontinuity in longitude values.

3.5.5.5.3.2 For IPPs north of N85° or south of S85

$$y_{pp} = \frac{|\varphi_{PQ}| - 85^\circ}{10^\circ}$$

$$x_{pp} = \frac{\lambda_{pp} - \lambda_3}{90^\circ} \times (1 - 2y_{pp}) + y_{pp}$$

where

λ_1 = longitude of the second IGP to the east of the IPP;

λ_2 = longitude of the second IGP to the west of the IPP;

λ_3 = longitude of the closest IGP to the west of the IPP; and

λ_4 = longitude of the closest IGP to the east of the IPP.

When three points are used for interpolation, the interpolated vertical ionospheric delay estimated is:

3.5.5.5.3.3 For points between S75° and N75°:

$$\tau_{vpp} = \sum_{k=1}^3 W_k \tau_{vk}$$

where

$$W_2 = y_{pp};$$

$$W_2 = 1 - X_{pp} - Y_{pp}; \text{ and}$$

$$W_3 = X_{pp}.$$

3.5.5.5.3.4 x_{pp} and y_{pp} are calculated as for four-point interpolation, except that λ_1 and φ_1 are always the longitude and latitude of IGP2, and λ_2 and φ_2 are the other longitude and latitude. IGP2 is always the vertex opposite the hypotenuse of the triangle defined by the three points, IGP1 has the same longitude as IGP2, and IGP3 has the same latitude as IGP2 (an example is shown in Figure B-14).

3.5.5.5.3.5 For points north of N75° and south of S75°, three-point interpolation is not supported.

3.5.5.5.4 Selection of ionospheric grid points (IGPs). The protocol for the selection of IGPs is:

a) For an IPP between N60° and S60°:

- i. if four IGPs that define a 5-degree-by-5-degree cell around the IPP are set to “1” in the IGP mask, they are selected; else,
- ii. if any three IGPs that define a 5-degree-by-5-degree triangle that circumscribes the IPP are set to “1” in the IGP mask, they are selected; else,
- iii. if any four IGPs that define a 10-degree-by-10-degree cell around the IPP are set to “1” in the IGP mask, they are selected; else,

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 119

- iv. if any three IGPs that define a 10-degree-by-10-degree triangle that circumscribes the IPP are set to “1” in the IGP mask, they are selected; else,
 - v. an ionospheric correction is not available.
- b) For an IPP between N60° and N75° or between S60° and S75°:
- i. if four IGPs that define a 5-degree-latitude-by-10-degree longitude cell around the IPP are set to “1” in the IGP mask, they are selected; else,
 - ii. if any three IGPs that define a 5-degree-latitude-by-10-degree longitude triangle that circumscribes the IPP are set to “1” in the IGP mask, they are selected; else,
 - iii. if any four IGPs that define a 10-degree-by-10-degree cell around the IPP are set to “1” in the IGP mask, they are selected; else,
 - iv. if any three IGPs that define a 10-degree-by-10-degree triangle that circumscribes the IPP are set to “1” in the IGP mask, they are selected; else,
 - v. an ionospheric correction is not available.
- c) For an IPP between N75° and N85° or between S75° and S85°:
- i. if the two nearest IGPs at 75° and the two nearest IGPs at 85° (separated by 30° longitude if Band 9 or 10 is used, separated by 90° otherwise) are set to “1” in the IGP mask, a 10-degree-by-10-degree cell is created by linearly interpolating between the IGPs at 85° to obtain virtual IGPs at longitudes equal to the longitudes of the IGPs at 75°; else,
 - ii. an ionospheric correction is not available.
- d) For an IPP north of N85°:
- i. if the four IGPs at N85° latitude and longitudes of W180°, W90°, 0° and E90° are set to “1” in the IGP mask, they are selected; else,
 - ii. an ionospheric correction is not available.
- e) For an IPP south of S85°:
- i. if the four IGPs at S85° latitude and longitudes of W140°, W50°, E40° and E130° are set to “1” in the IGP mask, they are selected; else,
 - ii. an ionospheric correction is not available.

Note. — This selection is based only on the information provided in the mask, without regard to whether the selected IGPs are monitored, “Not Monitored”, or “Do Not Use”. If any of the selected IGPs is identified as “Do Not Use”, an ionospheric correction is not available. If four IGPs are selected, and one of the four is identified as “Not Monitored”, then three-point interpolation is used if the IPP is within the triangular region covered by the three corrections that are provided.

3.5.5.6 Protection levels. The horizontal protection level (HPL) and the vertical protection level (VPL) are:

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 120

$$HPL_{SBAS} = \begin{cases} K_{H,NPA} \times d_{major} & \text{for en-route through non-precision approach (NPA) modes} \\ K_{H,PA} \times d_{major} & \text{for precision approach (PA) and approach with vertical guidance (APV) modes} \end{cases}$$

$$VPL_{SBAS} = K_{V,PA} \times d_v$$

where

$d_v^2 = \sum_{i=1}^N s_{v,i}^2 \sigma_i^2$ = variance of model distribution that overbounds the true error distribution in the vertical axis;

$$d_{major} = \sqrt{\frac{d_x^2 + d_y^2}{2}} + \sqrt{\left(\frac{d_x^2 - d_y^2}{2}\right)^2 + d_{xy}^2}$$

where

$d_x^2 = \sum_{i=1}^N s_{x,i}^2 \sigma_i^2$ = variance of model distribution that overbounds the true error distribution in the x axis;

$d_y^2 = \sum_{i=1}^N s_{y,i}^2 \sigma_i^2$ = variance of model distribution that overbounds the true error distribution in the y axis;

$d_{xy} = \sum_{i=1}^N s_{x,i} s_{y,i} \sigma_i^2$ = covariance of model distribution in the x and y axis;

where

$s_{x,i}$ = the partial derivative of position error in the x-direction with respect to pseudo-range error on the i^{th} satellite;

$s_{y,i}$ = the partial derivative of position error in the y-direction with respect to pseudo-range error on the i^{th} satellite;

$s_{v,i}$ = the partial derivative of position error in the vertical direction with respect to pseudo-range error on the i^{th} satellite; and

$$\sigma_i^2 = \sigma_{i,flt}^2 + \sigma_{i,UIRE}^2 + \sigma_{i,air}^2 + \sigma_{i,tropo}^2$$

The variances ($\sigma_{i,flt}^2$ and $\sigma_{i,UIRE}^2$) are defined in 3.5.5.6.2 and 3.5.5.6.3.1. The parameters ($\sigma_{i,air}^2$ and $\sigma_{i,tropo}^2$) are determined by the aircraft element (3.5.8.4.2 and 3.5.8.4.3).

The x and y axes are defined to be in the local horizontal plane, and the v axis represents local vertical.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 121

For a general least-squares position solution, the projection matrix S is:

$$S \equiv \begin{bmatrix} S_{x,1} & S_{x,2} & \dots & S_{x,N} \\ S_{y,1} & S_{y,2} & \dots & S_{y,N} \\ S_{v,1} & S_{v,2} & \dots & S_{v,N} \\ S_{t,1} & S_{t,2} & \dots & S_{t,N} \end{bmatrix} = (G^T \times W \times G)^{-1} \times G^T \times W$$

where

$$G_i = [-\cos E_{li} \cos A_{zi} \quad -\cos E_{li} \sin A_{zi} \quad -\sin E_{li} \quad 1] = i^{\text{th}} \text{ row of } G;$$

$$W^{-1} = \begin{bmatrix} w_1 & 0 & \dots & 0 \\ 0 & w_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \dots & \dots & w_i \end{bmatrix};$$

E_{li} = the elevation angle of the i^{th} ranging source (in degrees);

A_{zi} = the azimuth of the i^{th} ranging source taken counter-clockwise from the x axis in degrees; and

w_i = the inverse weight associated with satellite $i = \sigma_i^{-2}$.

Note 1.— To improve readability, the subscript i was omitted from the protection matrix's equation.

Note 2.— For an unweighted least-squares solution, the weighting matrix is an identity matrix ($w_i = 1$).

3.5.5.6.1 Definition of K values. The K values are:

$$K_{H,NPA} = 6.18;$$

$$K_{H,NPA} = 6.0; \text{ and}$$

$$K_{V,NPA} = 5.33.$$

3.5.5.6.2 Definition of fast and long-term correction error model. If fast corrections and long-term correction/GE ranging parameters are applied, and degradation parameters are applied:

$$\sigma_{i,flt}^2 = \begin{cases} [(\delta_{i,UDRE})(\delta_{UDRE}) + \varepsilon_{fc} + \varepsilon_{rrc} + \varepsilon_{ltc} + \varepsilon_{re}]^2, & \text{if } RSS_{UDRE} = 0 \text{ (Message Type 10)} \\ [(\delta_{i,UDRE})(\delta_{UDRE})]^2 + \varepsilon_{fc}^2 + \varepsilon_{rrc}^2 + \varepsilon_{ltc}^2 + \varepsilon_{re}^2, & \text{if } RSS_{UDRE} = 1 \text{ (Message Type 10)} \end{cases}$$

where

if using message Type 27, δ_{UDRE} is a region-specific term as defined in section 3.5.4.9,

if using message Type 28, δ_{UDRE} is a satellite-specific term as defined in section 3.5.5.6.2.5,

if using neither message, $\delta_{UDRE} = 1$.

If fast corrections and long-term corrections/GEO ranging parameters are applied, but degradation parameters are not applied:

$$\delta_{i,flt}^2 = [(\delta_{i,UDRE})(\delta_{UDRE}) + 8\text{m}]^2$$

3.5.5.6.2.1 Fast correction degradation. The degradation parameter for fast correction data is:

$$\varepsilon_{fc} = \frac{a(t - t_u + t_{lat})^2}{2}$$

where

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

t = the current time;

t_{iat} = (as defined in 3.5.4.7). t_u = (UDREI_i reference time): if IODF_j ≠ 3, the start time of the SNT 1-second epoch that is coincident with the start of the transmission of the message block that contains the most recent UDREI_i data (Type 2 to 6, or Type 24 messages) that matches the IODF_j of the fast correction being used. If IODF_j = 3, the start time of the epoch of the SNT 1-second epoch that is coincident with the start of transmission of the message that contains the fast correction for the ith satellite; and

Note.— For UDREs broadcast in Type 2 to 5, and Type 24 messages, t_u equals the time of applicability of the fast corrections since they are in the same message. For UDREs broadcast in Type 6 message and if the IODF = 3, t_u also equals the time of applicability of the fast corrections (t_{of}). For UDREs broadcast in Type 6 message and IODF ≠ 3, t_u is defined to be the time of transmission of the first bit of Type 6 message at the GEO.

3.5.5.6.2.2 Range rate correction degradation

3.5.5.6.2.2.1 If the RRC = 0, then $\epsilon_{rrc} = 0$.

3.5.5.6.2.2.2 If the RRC ≠ 0 and IODF ≠ 3, the degradation parameter for fast correction data is:

$$\epsilon_{rrc} = \begin{cases} 0, & \text{if } (\text{IODF}_{\text{current}} \cdot \text{IODF}_{\text{previous}}) \text{MOD} 3 = 1 \\ \left(\frac{a I_{fc}}{4} + \frac{B_{rrc}}{\Delta t} \right) (t - t_{of}), & \text{if } (\text{IODF}_{\text{current}} \cdot \text{IODF}_{\text{previous}}) \text{MOD} 3 \neq 1 \end{cases}$$

3.5.5.6.2.2.3 If RRC ≠ 0 and IODF = 3, the degradation parameter for range rate data is:

$$\epsilon_{rrc} = \begin{cases} 0, & \text{if } \left| \Delta t - \frac{I_{fc}}{2} \right| = 0 \\ \left(\frac{a \left| \Delta t - \frac{I_{fc}}{2} \right|}{2} + \frac{B_{rrc}}{\Delta t} \right) (t - t_{of}), & \text{if } \left| \Delta t - \frac{I_{fc}}{2} \right| \neq 0 \end{cases}$$

where

t = the current time;

IODF_{current} = IODF associated with most recent fast correction;

IODF_{previous} = IODF associated with previous fast correction;

$\Delta t = t_{i,of} - t_{i,of\text{-previous}}$; and

I_{fc} = the user time-out interval for fast corrections.;

3.5.5.6.2.3 Long-term correction degradation

3.5.5.6.2.3.1 Core satellite constellation(s)

3.5.5.6.2.3.1.1 For velocity code = 1, the degradation parameter for long-term corrections of satellite *i* is:

$$\epsilon_{ltc} = \begin{cases} 0, & \text{if } t_{i,LT} < t < t_{i,LT} + c_{ltc_v1} \\ c_{ltc_lsb} + c_{ltc_v1} \max(0, t_{i,LT} - t, t - t_{i,LT} - c_{ltc_v1}), & \text{otherwise} \end{cases}$$

3.5.5.6.2.3.1.2 For velocity code = 0, the degradation parameter for long-term corrections is:

$$\varepsilon_{ltc} = c_{ltc_v0} \left[\frac{t - t_{ltc}}{ltc_v0} \right]$$

where

t = the current time;

t_{ltc} = the time of transmission of the first bit of the long-term correction message at the GEO; and

[x] = the greatest integer less than x.

3.5.5.6.2.3.2 GEO satellites. The degradation parameter for long-term corrections is:

$$\varepsilon_{ltc} = \begin{cases} 0, & \text{if } t_{0,GEO} < t < t_{0,GEO} + I_{GEO} \\ c_{geo_lsb} + c_{geo_v1} \max(0, t_{0,GEO} - t, t - t_{0,GEO} - I_{geo}), & \text{otherwise} \end{cases}$$

where t = the current time

Note.— When long-term corrections are applied to a GEO satellite, the long-term correction degradation is applied and the GEO navigation message degradation is not applied.

3.5.5.6.2.4 Degradation for en-route through non-precision approach

$$\varepsilon_{er} = \begin{cases} 0, & \text{if neither fast nor long-term corrections have timed out for precision approach/approach with vertical guidance} \\ C_{er}, & \text{if fast or long-term corrections have timed out for precision approach/approach with vertical guidance} \end{cases}$$

3.5.5.6.2.5 UDRE degradation factor calculated with message Type 28 data. The δ UDRE is:

$$\delta_{UDRE} = \sqrt{I^T \cdot C \cdot I} + \varepsilon_c$$

where

$$I = \begin{bmatrix} i_x \\ i_y \\ i_z \\ 1 \end{bmatrix}$$

$\begin{bmatrix} i_x \\ i_y \\ i_z \end{bmatrix}$ = the unit vector from the user to the satellite in the WGS - 84 ECEF coordinate frame

$$C = R^T \cdot R$$

$$\varepsilon_c = C_{covariance} \cdot SF$$

$$SF = 2^{\text{scale exponent} - 5}$$

$$R = E \cdot SF$$

$$E = \begin{bmatrix} E_{1,1} & E_{1,2} & E_{1,3} & E_{1,4} \\ 0 & E_{2,2} & E_{2,3} & E_{2,4} \\ 0 & 0 & E_{3,3} & E_{3,4} \\ 0 & 0 & 0 & E_{4,4} \end{bmatrix}$$

	Technical provision for GNSS	Appendix-B	Page: 124

3.5.5.6.3 Definition of ionospheric correction error model

3.5.5.6.3.1 Broadcast ionospheric corrections. If SBAS-based ionospheric corrections are applied, σ^2_{UIRE} is:

$$\sigma^2_{UIRE} = F_{pp}^2 \times \sigma^2_{UIVE}$$

where

F_{pp} = (as defined in 3.5.5.5.2);

$$\sigma^2_{UIVE} = \sum_{n=1}^4 W_n \cdot \sigma^2_{n,ionogrid} \text{ or } \sigma^2_{UIVE} = \sum_{n=1}^4 W_n \cdot \sigma^2_{n,ionogrid}$$

using the same ionospheric pierce point weights (W_n) and grid points selected for the ionospheric correction (3.5.5.5).

If degradation parameters are used, for each grid point:

$$\sigma^2_{n,ionogrid} = \begin{cases} (\sigma_{n,GIVE} + \varepsilon_{iono})^2, & \text{if } RSS_{iono} = 0 \text{ (Type 10 message)} \\ \sigma^2_{n,GIVE} + \varepsilon^2_{iono}, & \text{if } RSS_{iono} = 1 \text{ (Type 10 message)} \end{cases}$$

where

$$\varepsilon_{iono} = C_{iono_step} \left[\frac{t - t_{iono}}{I_{iono}} \right] + C_{iono_ramp}(t - t_{iono})$$

t = the current time;

t_{iono} = the time of transmission of the first bit of the ionospheric correction message at the GEO; and

$[x]$ = the greatest integer less than x .

If degradation parameters are not used, for each grid point:

$$\sigma_{n,ionogrid} = \sigma_{n,GIVE}$$

Note.— For GLONASS satellites, both σ_{GIVE} and ε_{iono} parameters are to be multiplied by the square of the ratio of the GLONASS to the GPS frequencies ($f_{GLONASS}/f_{GPS}$)².

3.5.5.6.3.2 Ionospheric corrections. If SBAS-based ionospheric corrections are not applied, σ^2_{UIRE} is:

$$\sigma^2_{UIRE} = MAX \left\{ \left(\frac{T_{iono}}{5} \right)^2, (F_{pp} \cdot \tau_{vert})^2 \right\}$$

where

T_{iono} = the ionospheric delay estimated by the chosen model (GPS correction or other model);

F_{pp} = (as defined in 3.5.5.5.2);

$$\tau_{vert} = \begin{cases} 9m & 0 \leq |\phi_{pp}| \leq 20 \\ 4.5m & 20 \leq |\phi_{pp}| \leq 55 \text{ and} \\ 6m & 55 \leq |\phi_{pp}| \end{cases}$$

ϕ_{pp} = latitude of the ionospheric pierce point.

3.5.6 L1 SBAS Message Tables

Each SBAS message shall be coded in accordance with the corresponding message format defined in Tables B-75 through B-71. All signed parameters in these tables shall be represented in two's complement, with the sign bit occupying the MSB.

Note - The range for the signed parameters is smaller than indicated, as the maximum positive value is constrained to be one value less (the indicated value minus the resolution).

Table B-75. Type 0 “Do Not Use” message broadcast on L1

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
Reserved	212	—	—

Table B-76. Type 1 PRN mask message

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
---------------------	------------------	------------------------	-------------------

For each of 210 PRN code numbers

Mask value	1	0 or 1	1
IODP	2	0 to 3	1

Note.— All parameters are defined in 3.5.4.1.

Table B-77. Types 2 to 5 fast correction message

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
IODF _j	2	0 to 3	1
IODP	2	0 to 3	1
For 13 slots			
Fast correction (FC _i)	12	±256.000 m	0.125 m
For 13 slots			
UDREI _i	4	(see Table B-67)	(see Table B-67)

Notes.—

1. *The parameters IODF_j and FC_i are defined in 3.5.4.4.2.*
2. *The parameter IODP is defined in 3.5.4.1.*
3. *The parameter UDREI_i is defined in 3.5.4.5.*

Table B-78. Type 6 integrity message

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
IODF ₂	2	0 to 3	1
IODF ₃	2	0 to 3	1
IODF ₄	2	0 to 3	1
IODF ₅	2	0 to 3	1
For 51 satellites (ordered by PRN mask number)

E _{1,3}	10	±512	1
E _{1,4}	10	±512	1
E _{2,3}	10	±512	1
E _{2,4}	10	±512	1
E _{3,4}	10	±512	1

Notes.—

1. The parameters PRN mask number and IODP are defined in 3.5.4.1.
2. All other parameters are defined in 3.5.4.10.

3.5.7 L1 SBAS Non-Aircraft Elements

Note 1 - Depending on the level of service offered by a particular SBAS, different functions can be implemented as described in Chapter 3, 3.7.3.4.2.

Note 2 - The parameters that are referred to in this section are defined in 3.5.4

3.5.7.1 General

3.5.7.1.1 Required data and broadcast intervals. SBAS shall broadcast the data required for the supported functions as shown in Table B-92. If the SBAS broadcasts data that are not required for a particular function, the requirements for that data supporting other functions shall apply. The maximum interval between broadcasts for all data of each data type provided shall be as defined in Table B-92.

3.5.7.1.2 SBAS radio frequency monitoring. The SBAS shall monitor the SBAS satellite parameters shown in Table B-93 and take the indicated action.

Note - SBAS may broadcast null messages (Type 63 messages) in each time slot for which no other data are broadcast.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 135

3.5.7.1.3 “Do Not Use”. SBAS shall broadcast a “Do Not Use” message (Type 0 message) when necessary to inform users not to use the SBAS satellite ranging function and its broadcast data.

3.5.7.1.4 The Doppler shift in the GEO satellite signal seen at any fixed location within the GEO footprint for any GEO shall not exceed ± 450 Hz.

Note - This maximum Doppler shift corresponds approximately to the maximum GEO satellite orbit inclination that can be supported by the coding ranges for Type 9 and Type 17 messages.

3.5.7.1.5 Geostationary orbit (GEO) ranging function parameters. Each SBAS satellite shall broadcast geostationary orbit (GEO) ranging function parameters (defined in 3.5.4.2).

Note - It is necessary to broadcast geostationary orbit ranging function parameters even when a ranging function is not provided, so that airborne receivers may implement a positive identification of the broadcasting SBAS satellite. When ranging is not provided, the accuracy of the Type 17 data (and Type 9 data) only needs to support the acquisition of the satellite.

3.5.7.1.5.1 The error in the Doppler shift of a GEO satellite derived from any Type 9 message that has not timed out, with respect to the true GEO Doppler shift seen at any fixed location within the GEO footprint, shall not exceed ± 210 Hz.

3.5.7.1.6 Almanac data. Each SBAS satellite shall broadcast almanac data (defined in 3.5.4.3) for all SBAS satellites of the same service provider.

3.5.7.1.6.1 The error in the estimated position of the satellite derived from any Type 17 message broadcast within the previous 15 minutes, with respect to the true satellite position, shall not exceed 3 000 km.

3.5.7.1.6.2 The separation distance between the estimated position of the satellite derived from any Type 17 message broadcast within the previous 15 minutes and the position of the satellite derived from the GEO ranging parameters in any Type 9 message that has not timed out shall not exceed 200 km.

3.5.7.1.6.3 The error in the Doppler shift of a GEO satellite derived from any Type 17 message broadcast within the previous 15 minutes, with respect to the true GEO Doppler shift seen at any fixed location within the GEO footprint, shall not exceed ± 210 Hz.

3.5.7.1.6.4 SBAS shall not broadcast almanac data for any SBAS satellite from a different service provider for which the position estimated from the almanac data broadcast within the previous 15 minutes would be within 200 km of the position of any of its own GEOs as derived from the GEO ranging parameters from any Type 9 message that has not timed out.

3.5.7.1.6.5 Where the estimated position of a GEO satellite providing a ranging function, derived from the Type 17 message broadcast within the previous 15 minutes, is within 200 km of the position of another GEO satellite of the same service provider, derived from a Type 9 message for this GEO that has not timed out, the GEO UDRE value shall be set sufficiently large to account for the possibility that a user could misidentify the PRN of the GEO providing the ranging function.

3.5.7.1.6.6 The health and status parameter shall indicate the satellite status and the service provider identifier, as defined in 3.5.4.3.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 136

3.5.7.1.6.7 Unused almanac slots in Type 17 messages shall be coded with a PRN code number of “0”.

3.5.7.1.6.8 The service provider shall ensure the correctness of the service provider ID broadcast in any almanac.

3.5.7.2 Ranging function. If an SBAS provides an L1 SBAS ranging function, it shall comply with the requirements contained in this section in addition to the requirements of 3.5.7.1.

3.5.7.2.1 Performance requirements

Note - See Chapter 3, 3.7.3.4.3

3.5.7.2.2 Ranging function data. SBAS shall broadcast ranging function data such that the SBAS satellite position error projected on the line-of-sight to any user in the satellite footprint is less than 256 meters. Each SBAS satellite shall broadcast a URA representing an estimate of the standard deviation of the ranging errors referenced to SNT L1 SBAS.

3.5.7.3 GNSS satellite status function. If an SBAS provides a satellite status function, it shall also comply with the requirements contained in this section.

Note.— An SBAS may be able to provide integrity on some GPS satellites that are designated either marginal or unhealthy.

3.5.7.3.1 Performance of satellite status functions. Given any valid combination of active data, the probability of a horizontal error exceeding the HPL_{SBAS} (as defined in 3.5.5.6) for longer than 8 consecutive seconds shall be less than 10^{-7} in any hour, assuming a user with zero latency.

Note - Active data is defined to be data that have not timed out per 3.5.8.1.2. This requirement includes core satellite constellation(s) and SBAS failures.

3.5.7.3.2 PRN mask and Issue of data — PRN (IODP). SBAS shall broadcast a PRN mask and IODP (Type 1 message). The PRN mask values shall indicate whether or not data are being provided for each GNSS satellite. The IODP shall change when there is a change in the PRN mask. The change of IODP in Type 1 messages shall occur before the IODP changes in any other message. The IODP in Type 2 to 5, 7, 24, 25 and 28 messages shall equal the IODP broadcast in the PRN mask message (Type 1 message) used to designate the satellites for which data are provided in that message.

Table B-92. Data broadcast intervals and supported functions

<i>Data type</i>	<i>Maximum broadcast interval</i>	<i>Ranging</i>	<i>GNSS Satellite status</i>	<i>Basic differential correction</i>	<i>Precise differential correction</i>	<i>Associated Message types</i>
Clock-Ephemeris covariance matrix	120 s					28
SBAS in test mode	6 s					0
PRN mask	120 s		R	R	R	1
UDREI	6 s		R*	R	R	2 to 6, 24
Fast corrections	$I_{fc}/2$ (see Note 4)		R*	R	R	2 to 5, 24
Long-term corrections	120 s		R*	R	R	24, 25
GEO ranging function data	120 s	R	R	R	R	9
Fast correction degradation	120 s		R*	R	R	7
Degradation parameters	120 s				R	10
Ionospheric grid mask	300 s				R	18
Ionospheric corrections, GIVEI	300 s				R	26
Timing data	300 s	R (see Note 3)	R (see Note 3)	R (see Note 3)	R (see Note 3)	12
Almanac data	300 s	R	R	R	R	17
Service level	300 s					27

Notes.—

1. "R" indicates that the data must be broadcast to support the function.
2. "R*" indicates special coding as described in 3.5.7.3.3.
3. Type 12 messages are only required if data are provided for GLONASS satellites.
4. I_{fc} refers to the PA/APV time-out interval for fast corrections, as defined in Table B-95.

Table B-93. SBAS L1 radio frequency monitoring

<i>Parameter</i>	<i>Reference</i>	<i>Alarm limit</i>	<i>Required action</i>
Signal power level	Chapter 3, 3.7.3.4.5.3	minimum specified power maximum specified power (<i>Note 2</i>)	Cease ranging function (Note 1). Cease broadcast.
Modulation	Chapter 3, 3.7.3.4.5.5	monitor for waveform distortion	Cease L1 ranging function (Note 1).
SNT-to-GPS time	Chapter 3, 3.7.3.4.7	N/A (<i>Note 3</i>)	Cease L1 ranging function unless σ_{UDRE} reflects error.
Carrier frequency stability	3.5.2.1	N/A (<i>Note 3</i>)	Cease L1 ranging function unless σ_{UDRE} reflects error.
Code/frequency coherence	3.5.2.4	N/A (<i>Note 3</i>)	Cease L1 ranging function unless σ_{UDRE} reflects error.
Maximum code phase deviation	3.5.2.6	N/A (<i>Notes 2 and 3</i>)	Cease L1 ranging function unless σ_{UDRE} reflects error.
Convolutional encoding	3.5.2.9	all transmit messages are erroneous	Cease broadcast.

Notes.—

1. *Ceasing the ranging function is accomplished by broadcasting a URA and σ^2_{UDRE} of “Do Not Use” for that SBAS satellite.*
2. *These parameters can be monitored by their impact on the received signal quality (C/N_0 impact), since that is the impact on the user.*
3. *Alarm limits are not specified because the induced error is acceptable, provided it is represented in the σ^2_{UDRE} and URA parameters. If the error cannot be represented, the ranging function must cease.*

3.5.7.3.2.1 When the PRN mask is changed, SBAS should repeat the Type 1 message several times before referencing it in other messages to ensure that users receive the new mask.

3.5.7.3.3 Integrity data. If SBAS does not provide the basic differential correction function, it shall transmit fast corrections, long-term corrections and fast correction degradation parameters coded to zero for all visible satellites indicated in the PRN mask.

3.5.7.3.3.1 If SBAS does not provide the basic differential correction function, SBAS shall indicate that the satellite is unhealthy (“Do Not Use”) if the pseudo-range error exceeds 150 meters.

3.5.7.3.3.2 If SBAS does not provide the basic differential correction function, SBAS shall indicate that the satellite is “Not Monitored” if the pseudo-range error cannot be determined.

3.5.7.3.3.3 If SBAS does not provide the basic differential correction function, SBAS shall transmit a UDREI_i of 13 if the satellite is not “Do Not Use” or “Not Monitored”.

3.5.7.3.3.4 The IODF_j parameter in Type 2 to 5, 6 or 24 messages shall be equal to 3.

3.5.7.4 Basic differential correction function. If an SBAS provides a basic differential correction function, it shall comply with the requirements contained in this section in addition to the GNSS satellite status function requirements defined in 3.5.7.3.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 139

3.5.7.4.1 Performance of basic differential correction function. Given any valid combination of active data, the probability of a horizontal error exceeding the HPL_{SBAS} (as defined in 3.5.5.6) for longer than 8 consecutive seconds shall be less than 10^{-7} in any hour, assuming a user with zero latency.

Note - Active data is defined to be data that has not timed out per 3.5.8.1.2. This requirement includes core satellite constellation(s) and SBAS failures.

3.5.7.4.2 Long-term corrections. Except for SBAS satellites from the same service provider, SBAS shall determine and broadcast long-term corrections for each visible GNSS satellite (see *Note*) indicated in the PRN mask (PRN mask value equal to “1”). The long-term corrections shall be such that the core satellite constellation(s) satellite position error projected on the line-of-sight to any user in the satellite footprint after application of these long-term corrections is less than 256 meters. For each GLONASS satellite, SBAS shall translate satellite coordinates into WGS-84 as defined in 3.1.2.5.2 prior to determining the long-term corrections. For each GPS satellite, the broadcast IOD shall match both the GPS IODE and 8 LSBs of IODC associated with the clock and ephemeris data used to compute the corrections (3.1.1.3.1.4 and 3.1.1.3.2.2). Upon transmission of a new ephemeris by a GPS satellite, SBAS shall continue to use the old ephemeris to determine the fast and long-term error corrections for at least 2 minutes and not more than 4 minutes. For each GLONASS satellite, SBAS shall compute and broadcast an IOD that consists of a latency and a validity interval as defined in 3.5.4.4.1.

Note -The criteria for satellite visibility include the locations of reference stations and the achieved mask angle at those locations.

3.5.7.4.2.1 To ensure accurate range rate corrections, SBAS should minimize discontinuities in the satellite ephemerides after application of long-term corrections.

3.5.7.4.3 Fast corrections. SBAS shall determine fast corrections for each visible GNSS satellite indicated in the PRN mask (PRN mask value equal to “1”). Unless the $IODF_j = 3$, each time any fast correction data in Type j ($j = 2, 3, 4$ or 5) message changes, the $IODF_j$ shall sequence “0, 1, 2, 0, ...”.

Note - If there is an alarm condition, the $IODF_j$ may equal 3 (see 3.5.7.4.5).

3.5.7.4.4 Timing data. If data are provided for GLONASS, SBAS shall broadcast the timing message (Type 12 message) including GLONASS time offset as defined in Table B-44.

3.5.7.4.5 Integrity data. For each satellite for which corrections are provided, SBAS shall broadcast integrity data ($UDRE_i$ and, optionally, Type 27 or 28 message data to calculate $\delta UDRE$) such that the integrity requirement in 3.5.7.4.1 is met. If the fast corrections or long-term corrections exceed their coding range, SBAS shall indicate that the satellite is unhealthy (“Do Not Use”). If $\sigma^2_{i,UDRE}$ cannot be determined, SBAS shall indicate that the satellite is “Not Monitored”.

If Type 6 message is used to broadcast $\sigma^2_{i,UDRE}$, then:

- a) the $IODF_j$ shall match the $IODF_j$ for the fast corrections received in Type j message to which the $\sigma^2_{i,UDRE}$ apply; or
- b) the $IODF_j$ shall equal 3 if the $\sigma^2_{i,UDRE}$ apply to all valid fast corrections received in Type j message which have not timed out.

3.5.7.4.6 Degradation data. SBAS shall broadcast degradation parameters (Type 7 message) to indicate the applicable time out interval for fast corrections and ensure that the integrity requirement in 3.5.7.4.1 is met.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 140

3.5.7.5 Precise differential correction function. If SBAS provides a precise differential correction function, it shall comply with the requirements contained in this section in addition to the basic differential correction function requirements in 3.5.7.4.

3.5.7.5.1 Performance of precise differential correction function. Given any valid combination of active data, the probability of an out-of-tolerance condition for longer than the relevant time-to-alert shall be less than 2×10^{-7} during any approach, assuming a user with zero latency. The time-to-alert shall be 5.2 seconds for an SBAS that supports precision approach operations, and 8 seconds for an SBAS that supports APV or NPA operations. An out-of-tolerance condition shall be defined as a horizontal error exceeding the HPL_{SBAS} or a vertical error exceeding the VPL_{SBAS} (as defined in 3.5.5.6). When an out-of-tolerance condition is detected, the resulting alert message (broadcast in a Type 2 to 5 and 6, 24, 26 or 27 messages) shall be repeated three times after the initial notification of the alert condition for a total of four times in 4 seconds.

Note 1 - Active data is defined to be data that has not timed out per 3.5.8.1.2. This requirement includes core satellite constellation(s) and SBAS failures.

Note 2 - Subsequent messages can be transmitted at the normal update rate.

3.5.7.5.2 Ionospheric grid point (IGP) mask. SBAS shall broadcast an IGP mask and $IODI_k$ (up to 11 Type 18 messages, corresponding to the 11 IGP bands). The IGP mask values shall indicate whether or not data are being provided for each IGP. If IGP Band 9 is used, then the IGP mask values for IGPs north of $55^\circ N$ in Bands 0 through 8 shall be set to “0”. If IGP Band 10 is used, then the IGP mask values for IGPs south of $55^\circ S$ in Bands 0 through 8 shall be set to “0”. The $IODI_k$ shall change when there is a change of IGP mask values in the k^{th} band. The new IGP mask shall be broadcast in a Type 18 message before it is referenced in a related Type 26 message. The $IODI_k$ in Type 26 message shall equal the $IODI_k$ broadcast in the IGP mask message (Type 18 message) used to designate the IGPs for which data are provided in that message.

3.5.7.5.2.1 When the IGP mask is changed, SBAS should repeat the Type 18 message several times before referencing it in a Type 26 message to ensure that users receive the new mask. The same $IODI_k$ should be used for all bands.

3.5.7.5.3 Ionospheric corrections. SBAS shall broadcast ionospheric corrections for the IGPs designated in the IGP mask (IGP mask values equal to “1”).

3.5.7.5.4 Ionospheric integrity data. For each IGP for which corrections are provided, SBAS shall broadcast GIVEI data such that the integrity requirement in 3.5.7.5.1 is met. If the ionospheric correction or $\sigma^2_{i,GIVE}$ exceed their coding range, SBAS shall indicate the status “Do Not Use” (designated in the correction data, 3.5.4.6) for the IGP. If $\sigma^2_{i,GIVE}$ cannot be determined, SBAS shall indicate that the IGP is “Not Monitored” (designated in the GIVEI coding).

3.5.7.5.5 Degradation data. SBAS shall broadcast degradation parameters (Type 10 message) such that the integrity requirement in 3.5.7.5.1 is met.

3.5.7.6 Optional Functions

3.5.7.6.1 Timing data. If UTC time parameters are broadcast, they shall be as defined in 3.5.4.8 (Type 12 message).

3.5.7.6.2 Service indication. If service indication data are broadcast, they shall be as defined in 3.5.4.9 (Type 27 message) and Type 28 messages shall not be broadcast. The IODS in all Type 27 messages shall increment when there is a change in any Type 27 message data.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 141

3.5.7.6.3 Clock-ephemeris covariance matrix. If clock-ephemeris covariance matrix data are broadcast, they shall be broadcast for all monitored satellites as defined in 3.5.4.10 (Type 28 message) and Type 27 messages shall not be broadcast.

3.5.7.7 Monitoring

3.5.7.7.1 SBAS radio frequency monitoring. The SBAS shall monitor the SBAS satellite parameters shown in Table B-55 and take the indicated action.

Note.— In addition to the radio frequency monitoring requirements in this section, it will be necessary to make special provisions to monitor pseudo-range acceleration specified in Chapter 3, 3.7.3.4.3.5, and carrier phase noise specified in 3.5.2.2 and correlation loss in 3.5.2.5, unless analysis and testing shows that these parameters cannot exceed the stated limits.

3.5.7.7.2 Data monitoring. SBAS shall monitor the satellite signals to detect conditions that will result in improper operation of differential processing for airborne receivers with the tracking performance defined in Attachment D, 8.11.

3.5.7.7.2.1 The ground subsystem shall use the strongest correlation peak in all receivers used to generate the pseudo-range corrections.

3.5.7.7.2.2 The ground subsystem shall also detect conditions that cause more than one zero crossing for airborne receivers that use the Early-Late discriminator function as defined in Attachment D, 8.11.

3.5.7.7.2.3 The monitor action shall be to set UDRE to “Do Not Use” for the satellite.

3.5.7.7.2.4 SBAS shall monitor all active data that can be used by any user within the service area.

3.5.7.7.2.5 SBAS shall raise an alarm within 5.2 seconds if any combination of active data and GNSS signals-in-space results in an out-of-tolerance condition for precision approach (3.5.7.5.1).

3.5.7.7.2.6 SBAS shall raise an alarm within 8 seconds if any combination of active data and GNSS signals-in-space results in an out-of-tolerance condition for en-route through APV I (3.5.7.4.1).

Note - The monitoring applies to all failure conditions, including failures in core satellite constellation(s) or SBAS satellites. This monitoring assumes that the aircraft element complies with the requirements of RTCA/DO-229D with Change 1, except as superseded by 3.5.8 and Attachment D, 8.11.

3.5.7.8 Robustness to core satellite constellation(s) failures. Upon occurrence of a core satellite constellation(s) satellite anomaly, SBAS shall continue to operate normally using the available healthy satellite signals that can be tracked.

3.5.8 L1 SBAS Aircraft Elements

Note 1 - The parameters that are referred to in this section are defined in 3.5.4.

Note 2 - Some of the requirements of this section may not apply to equipment that integrates additional navigation sensors, such as equipment that integrates SBAS with inertial navigation sensors.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 142

3.5.8.1 SBAS-capable GNSS receiver. Except as specifically noted, the SBAS-capable GNSS receiver shall process the signals of the SBAS and meet the requirements specified in 3.1.3.1 (GPS receiver) and/or 3.2.3.1 (GLONASS receiver).

Pseudo-range measurements for each satellite shall be smoothed using carrier measurements and a smoothing filter which deviates less than 0.25 meter within 200 seconds after initialization, relative to the steady-state response of the filter defined in 3.6.5.1 in the presence of drift between the code phase and integrated carrier phase of up to 0.018 meter per second.

3.5.8.1.1 GEO satellite acquisition. The receiver shall be able to acquire and track GEO satellites for which a stationary receiver at the user receiver location would experience a Doppler shift as large as ± 450 Hz.

3.5.8.1.2 Conditions for use of data. The receiver shall use data from an SBAS message only if the CRC of this message has been verified. Reception of a Type 0 message from an SBAS satellite shall result in deselection of that satellite for at least one minute and all data from that satellite shall be discarded, except that there is no requirement to discard data from Type 12 and Type 17 messages. For GPS satellites, the receiver shall apply long-term corrections only if the IOD matches both the IODE and 8 least significant bits of the IODC. For GLONASS satellites, the receiver shall apply long-term corrections only if the time of reception (t_r) of the GLONASS ephemeris is inside the following IOD validity interval, as defined in 3.5.4.4.1:

$$t_{LT} - L - V \leq t_r \leq t_{LT} - L$$

Note 1 - For SBAS satellites, there is no mechanism that links GEO ranging function data (Type 9 message) and long-term corrections.

Note 2 - This requirement does not imply that the receiver has to stop tracking the SBAS satellite.

3.5.8.1.2.1 SBAS satellite identification. Upon acquisition or re-acquisition of an SBAS satellite, the receiver shall not use SBAS satellite data unless the calculated separation between the satellite position derived from its GEO ranging function parameters and the satellite position derived from the almanac message most recently received from the same service provider within the last 15 minutes is less than 200 km.

Note - This check ensures that a receiver will not mistake one SBAS satellite for another due to cross-correlation during acquisition or re-acquisition.

3.5.8.1.2.2 The receiver shall use integrity or correction data only if the IODP associated with that data matches the IODP associated with the PRN mask.

3.5.8.1.2.3 The receiver shall use SBAS-provided ionospheric data (IGP vertical delay estimate and $GIVEI_i$) only if the $IODI_k$ associated with that data in a Type 26 message matches the $IODI_k$ associated with the relevant IGP band mask transmitted in a Type 18 message.

3.5.8.1.2.4 The receiver shall use the most recently received integrity data for which the $IODF_j$ equals 3 or the $IODF_j$ matches the $IODF_j$ associated with the fast correction data being applied (if corrections are provided).

3.5.8.1.2.5 The receiver shall apply any regional degradation to the $\sigma_{1,UDRE}^2$ as defined by a Type 27 service message. If a Type 27 message with a new IODS indicates a higher δ_{UDRE} for the user location, the higher δ_{UDRE} shall be applied immediately. A lower δ_{UDRE} in a new Type 27 message shall not be applied until the complete set of messages with the new IODS has been received.

3.5.8.1.2.6 The receiver shall apply satellite-specific degradation to the $\sigma_{i,UDRE}^2$ as defined by a Type 28 clock-ephemeris covariance matrix message. The δ_{UDRE} derived from a Type 28 message with an IODP matching that of the PRN mask shall be applied immediately.

3.5.8.1.2.7 In the event of a loss of four successive SBAS messages during an SBAS-based approach operation with a HAL of 40 m or a VAL of 50 m or less, the receiver shall invalidate all UDREI data from that SBAS satellite.

3.5.8.1.2.8 The receiver shall not use a broadcast data parameter after it has timed out as defined in Table B-94.

3.5.8.1.2.9 The receiver shall not use a fast correction if t for the associated RRC exceeds the time-out interval for fast corrections, or if the age of the RRC exceeds $8t$.

3.5.8.1.2.10 The calculation of the RRC shall be reinitialized if a “Do Not Use” or “Not Monitored” indication is received for that satellite.

3.5.8.1.2.11 For SBAS-based precision approach or APV operations, the receiver shall only use satellites with elevation angles at or above 5 degrees.

3.5.8.1.2.12 The receiver shall no longer support SBAS-based precision approach or APV operation using a particular satellite if the $UDREI_i$ received is greater than or equal to 12.

Table B-94. Data time-out intervals

<i>Data</i>	<i>Associated message types</i>	<i>En-route, terminal, NPA time-out</i>	<i>Precision approach, APV time-out</i>
Clock-ephemeris covariance matrix	28	360	240
SBAS in test mode	0	N/A	N/A
PRN mask	1	600 s	600 s
UDREI	2 to 6, 24	18 s	12 s
Fast corrections	2 to 5, 24	(see Table B-95)	(see Table B-95)
Long-term corrections	24, 25	360 s	240 s
GEO ranging function data	9	360 s	240 s
Fast correction degradation	7	360 s	240 s
Degradation parameters	10	360 s	240 s
Ionospheric grid mask	18	1 200 s	1 200 s
Ionospheric corrections, GIVEI	26	600 s	600 s
Timing data	12	86 400 s	86 400 s
GLONASS time offset	12	600 s	600 s
Almanac data	17	None	None
Service level	27	86 400 s	86 400 s

Note.— The time-out intervals are defined from the end of the reception of a message.

Table B-95. Fast correction time-out interval evaluation

<i>Fast correction degradation factor indicator (a_{i_j})</i>	<i>NPA time-out interval for fast corrections (I_{fc})</i>	<i>PA/APV time-out interval for fast corrections (I_{fc})</i>
0	180 s	120 s
1	180 s	120 s
2	153 s	102 s
3	135 s	90 s
4	135 s	90 s
5	117 s	78 s
6	99 s	66 s
7	81 s	54 s
8	63 s	42 s
9	45 s	30 s
10	45 s	30 s
11	27 s	18 s
12	27 s	18 s
13	27 s	18 s
14	18 s	12 s
15	18 s	12 s

3.5.8.2 Ranging Function

3.5.8.2.1 Precision approach and APV operations. The root-mean-square (1 sigma) of the total airborne error contribution to the error in a corrected pseudo-range for an SBAS satellite at the minimum received signal power level (Chapter 3, 3.7.3.4.4.3) under the worst interference environment as defined in 3.7 shall be less than or equal to 1.8 meters, excluding multipath effects, tropospheric and ionospheric residual errors.

Note - The aircraft element will bound the errors caused by multipath and troposphere (3.5.8.4.1). For the purpose of predicting service, the multipath error is assumed to be less than 0.6 meters (1 sigma).

3.5.8.2.2 Departure, en-route, terminal, and non-precision approach operations. The root-mean-square (1 sigma) of the total airborne contribution to the error in a corrected pseudo-range for an SBAS satellite at the minimum received signal power level (Chapter 3, 3.7.3.4.4.3) under the worst interference environment as defined in 3.7 shall be less than or equal to 5 meters, excluding multipath, tropospheric and ionospheric errors.

3.5.8.2.3 SBAS satellite position

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 145

3.5.8.2.3.1 Position computation. The receiver shall decode Type 9 message and determine the code phase offset and position (X_G , Y_G , Z_G) of the SBAS satellite.

3.5.8.2.3.2 SBAS satellite identification. The receiver shall discriminate between SBAS satellites.

Note - This requirement applies to false acquisition of a satellite due to cross-correlation.

3.5.8.2.4 Almanac data

3.5.8.2.4.1 The almanac data provided by the SBAS should be used for acquisition.

Note. — Health and status information provided in the GEO almanac data does not override or invalidate data provided in other SBAS messages. The use of bits 0 to 2 by airborne equipment is optional; there are no requirements covering their usage.

3.5.8.3 GNSS satellite status function. The receiver shall exclude satellites from the position solution if they are identified as “Do Not Use” by SBAS. If SBAS-provided integrity is used, the receiver shall not be required to exclude GPS satellites based on the GPS-provided ephemeris health flag as required in 3.1.3.1.1 or to exclude GLONASS satellites based on GLONASS-provided ephemeris health flag as required in 3.2.3.1.1.

Note 1.— In the case of a satellite designated marginal or unhealthy by the core satellite constellation(s) health flag, SBAS may be able to broadcast ephemeris and clock corrections that will allow the user to continue using the satellite.

Note 2.— If satellites identified as “Not Monitored” by SBAS are used in the position solution, integrity is not provided by SBAS. ABAS or GBAS may be used to provide integrity, if available.

3.5.8.4 Basic and Precise Differential Functions

3.5.8.4.1 Core satellite constellation(s) ranging accuracy. The root-mean-square (1 sigma) of the total airborne contribution to the error in a corrected pseudo-range for a GPS satellite at the minimum and maximum received signal power level (Chapter 3, 3.7.3.1.7.4) under the worst interference environment as defined in 3.7 shall be less than or equal to 0.36 meters for minimum signal level and 0.15 meters for maximum signal level, excluding multipath effects, tropospheric and ionospheric residual errors. The RMS of the total airborne contribution to the error in a corrected pseudo-range for a GLONASS satellite at the minimum received signal power level (Chapter 3, 3.2.5.4) under the worst interference environment as defined in 3.7 shall be less than or equal to 0.8 meters, excluding multipath effects, tropospheric and ionospheric residual errors.

3.5.8.4.2 Precision approach and APV operations

3.5.8.4.2.1 The receiver shall obtain correction and integrity data for all satellites in the position solution from the same SBAS signal (PRN code).

3.5.8.4.2.2 The receiver shall compute and apply long-term corrections, fast corrections, range rate corrections and the broadcast ionospheric corrections. For GLONASS satellites, the ionospheric corrections received from the SBAS shall be multiplied by the square of the ratio of GLONASS to GPS frequencies ($f_{GLONASS}/f_{GPS}$)².

3.5.8.4.2.3 The receiver shall use a weighted-least-squares position solution.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 146

3.5.8.4.2.4 The receiver shall apply a tropospheric model such that residual pseudo-range errors have a mean value (μ) less than 0.15 meters and a 1 sigma deviation less than 0.07 meters.

Note.— A model was developed that meets this requirement. Guidance is provided in Attachment D, 6.5.4.

3.5.8.4.2.5 The receiver shall compute and apply horizontal and vertical protection levels defined in 3.5.5.6. In this computation, $\sigma_{i,tropo}$ shall be:

$$\frac{1.001}{\sqrt{0.002001 + \sin^2(\theta_i)}} \times 0.12m$$

where θ_i is the elevation angle of the i^{th} satellite

In addition, $\sigma_{i,air}$ shall satisfy the condition that a normal distribution with zero mean and a standard deviation equal to $\sigma_{i,air}$ bounds the error distribution for residual aircraft pseudo-range errors as follows:

$$\int_y^\infty f_n(x) dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \frac{y}{\sigma} \geq 0$$

$$\int_{-\infty}^{-y} f_n(x) dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \frac{y}{\sigma} \geq 0$$

where

$f_i(x)$ = probability density function of the residual aircraft pseudo-range error and

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^\infty e^{-\frac{t^2}{2}} dt$$

Note - The standard allowance for airborne multipath defined in 3.6.5.5.1 may be used to bound the multipath errors

3.5.8.4.2.6 The parameters that define the approach path for a single precision approach or APV shall be contained in the FAS data block.

Note 1 The FAS path is a line in space defined by the landing threshold point/fictitious threshold point (LTP/FTP), flight path alignment point (FPAP), threshold crossing height (TCH) and glide path angle (GPA). The local level plane for the approach is a plane perpendicular to the local vertical passing through the LTP/FTP (i.e. tangent to the ellipsoid at the LTP/FTP). Local vertical for the approach is normal to the WGS-84 ellipsoid at the LTP/FTP. The glide path intercept point (GPIP) is where the final approach path intercepts the local level plane.

Note 2.— For SBAS, FAS data blocks are stored in airborne databases. The format of the data for validation of a cyclic redundancy check is shown in Attachment D, 6.6. It differs from the GBAS FAS data block in 3.6.4.5.

3.5.8.4.2.6.1 L1 SBAS FAS data block parameters shall be as follows (see Table B-96):

Note 1.— See 3.5.15.3.5 for the definitions of operation type, SBAS service provider ID and approach performance designator applicable to DFMC SBAS receivers.

Note 2.— “L1 SBAS receivers” refers to receivers that meet the specifications of RTCA/DO-229.

Operation type: straight-in approach procedure or other operation types applicable to L1 SBAS receivers.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 147

Coding: 0 = straight-in approach procedure
1 to 15= spare

SBAS service provider ID: shall indicates the service provider associated with this FAS data block.

Coding: 0-13 = See Table B-56.

14 = FAS data block is to be used with GBAS only.

15 = FAS data block can be used with any SBAS service provider.

Airport ID: the three- or four-letter designator used to designate an airport.

Coding: Each character is coded using the lower 6 bits of its IA-5 representation. For each character, b_1 is transmitted first, and 2 zero bits are appended after b_6 , so that 8 bits are transmitted for each character. Only upper case letters, numeric digits and IA-5 “space” are used. The rightmost character is transmitted first. For a three-character airport ID, the rightmost (first transmitted) character shall be IA-5 “space”.

Runway number: the runway orientation, point-in- space final approach course, or SBAS circling only procedure course rounded to the nearest 10 degrees and truncated to two characters.

Coding: 01 to 36 = runway number

Note - For heliport operations, the runway number value is the integer nearest to one tenth of the final approach course, except when that integer is zero, in which case the runway number is 36.

Runway letter: the one-letter designator used, as necessary, to differentiate between parallel runways.

Coding: 0 = no letter
1 = R (right)
2 = C (centre)
3 = L (left)

Approach performance designator: this field ~~is~~ shall not be used by L1 SBAS receivers.

Table B-96. Final approach segment (FAS) data block

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
Operation type	4	0 to 15	1
SBAS service provider ID	4	0 to 15	1
Airport ID	32	—	—
Runway number	6	01 to 36	1
Runway letter	2	—	—
Approach performance designator	3	0 to 7	1
Route indicator	5	—	—
Reference path data selector	8	0 to 48	1
Reference path identifier	32	—	—
LTP/FTP latitude	32	±90.0°	0.0005 arcsec
LTP/FTP longitude	32	±180.0°	0.0005 arcsec
LTP/FTP height	16	−512.0 to 6 041.5 m	0.1 m
ΔFPAP latitude	24	±1.0°	0.0005 arcsec
ΔFPAP longitude	24	±1.0°	0.0005 arcsec
Approach TCH (<i>Note 1</i>)	15	0 to 1 638.35 m or 0 to 3 276.7 ft	0.05 m or 0.1 ft
Approach TCH units selector	1	—	—
Glide path angle (GPA)	16	0 to 90.0°	0.01°
Course width	8	80 to 143.75 m	0.25 m
ΔLength offset	8	0 to 2 032 m	8 m
Horizontal alert limit (HAL)	8	0 to 51.0 m	0.2 m
Vertical alert limit (VAL) (<i>Note 2</i>)	8	0 to 51.0 m	0.2 m
Final approach segment CRC	32		—

Note 1.— Information can be provided in either feet or metres as indicated by the approach TCH unit selector.

Note 2.— A VAL of 0 indicates that the vertical deviations cannot be used (i.e., a lateral only approach). This does not preclude providing advisory vertical guidance on such approaches, refer to FAA AC 20-138.

Route indicator: a “blank” or the one-letter identifier used to differentiate between multiple procedures to the same runway end.

Note - Procedures are considered to be different even if they only differ by the missed approach segment.

Coding: The letter is coded using bits b₁ through b₅ of its IA-5 representation. Bit b₁ is transmitted first. Only upper case letters, excluding “I” and “O”, or IA-5 “space” (blank) are used. Blank indicates that there is only one procedure to the runway end. For multiple procedures to the same runway end, the route indicator is coded using a letter starting from Z and moving backward in the alphabet for additional procedures.

Reference path data selector (RPDS): this field is not used by SBAS.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 149

Reference path identifier (RPI): four characters used to uniquely designate the reference path. The four characters consist of three alphanumeric characters plus a blank or four alphanumeric characters.

Note - The best industry practice matches the 2nd and 3rd character encoding to the encoded runway number. The last character is a letter starting from A or a “blank.”

Coding: Each character is coded using bits b_1 through b_6 of its IA-5 representation. For each character, b_1 is transmitted first, and 2 zero bits are appended after b_6 so that 8 bits are transmitted for each character. Only upper case letters, numeric digits and IA-5 “space” are used. The rightmost character is transmitted first. For a three-character reference path identifier, the rightmost (first transmitted) character shall be IA-5 “space”.

Note - The LTP/FTP is a point over which the FAS path passes at a height above the LTP/FTP height specified by the TCH.

LTP/FTP latitude: the latitude of the LTP/FTP point in arc seconds.

Coding: positive value denotes north latitude.
negative value denotes south latitude.

LTP/FTP longitude: the longitude of the LTP/FTP point in arc seconds.

Coding: positive value denotes east longitude.
negative value denotes west longitude.

LTP/FTP height: the height of the LTP/FTP above the WGS-84 ellipsoid.

Coding: This field is coded as an unsigned fixed-point number with an offset of -512 meters. A value of zero in this field places the LTP/FTP 512 meters below the earth ellipsoid.

Note.— The FPAP is a point at the same height as the LTP/FTP that is used to define the alignment of the approach. The origin of angular deviations in the lateral direction is defined to be 305 meters (1 000 ft) beyond the FPAP along the lateral FAS path. For an approach aligned with the runway, the FPAP is at or beyond the stop end of the runway.

Δ FPAP latitude: the difference of latitude of the runway FPAP from the LTP/FTP in arc seconds.

Coding: Positive value denotes the FPAP latitude north of LTP/FTP latitude.
Negative value denotes the FPAP latitude south of the LTP/FTP latitude.

Δ FPAP longitude: the difference of longitude of the runway FPAP from the LTP/FTP in arc seconds.

Coding: Positive value indicates the FPAP longitude east of LTP/FTP longitude.
Negative value indicates the FPAP longitude west of LTP/FTP longitude.

Approach TCH: the height of the FAS path above the LTP/FTP defined in either feet or meters as indicated by the TCH units selector.

Approach TCH units selector: the units used to describe the TCH.

Coding: 0 = feet
1 = meters

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 150

Glide path angle (GPA): the angle of the FAS path with respect to the horizontal plane tangent to the WGS-84 ellipsoid at the LTP/FTP.

Course width: the lateral displacement from the path defined by the FAS at the LTP/FTP at which full-scale deflection of a course deviation indicator is attained.

Coding: This field is coded as an unsigned fixed-point number with an offset of 80 meters. A value of zero in this field indicates a course width of 80 meters at the LTP/FTP.

Length offset: the distance from the stop end of the runway to the FPAP.

Coding: 1111 1111 = not provided

HAL: Horizontal alert limit to be used during the approach in meters.

VAL: Vertical alert limit to be used during the approach in meters.

Final approach segment CRC: the 32-bit CRC appended to the end of each FAS data block in order to ensure approach data integrity. The 32-bit final approach segment CRC shall be calculated in accordance with 3.9. The length of the CRC code shall be $k = 32$ bits.

The CRC generator polynomial shall be:

$$G(x) = x^{32} + x^{31} + x^{24} + x^{22} + x^{16} + x^{14} + x^8 + x^7 + x^5 + x^3 + x + 1$$

The CRC information field, $M(x)$, shall be:

$$M(x) = \sum_{i=1}^{288} m_i x^{288-i} = m_1 x^{287} + m_2 x^{286} + \dots + m_{288} x^0$$

$M(x)$ shall be formed from all bits of the associated FAS data block, excluding the CRC. Bits shall be arranged in the order transmitted, such that m_1 corresponds to the LSB of the operation type field, and m_{288} corresponds to the MSB of the Vertical Alert Limit (VAL) field. The CRC shall be ordered such that r_1 is the LSB and r_{32} is the MSB.

3.5.8.4.2.6.2 For precision approach and APV operations, the service provider ID broadcast Type 17 message shall be identical to the service provider ID in the FAS data block, except if ID equals 15 in the FAS data block.

Note - If the service provider ID in the FAS data block equals 15, then any service provider can be used. If the service provider ID in the FAS data block equals 14, then SBAS precise differential corrections cannot be used for the approach.

3.5.8.4.2.6.3 SBAS FAS data points accuracy. The survey error of all the FAS data points, relative to WGS-84, shall be less than 0.25 meters vertical and 1 meter horizontal.

3.5.8.4.3 Departure, en-route, terminal, and non-precision approach operations

3.5.8.4.3.1 The receiver shall compute and apply long-term corrections, fast corrections and range rate corrections.

3.5.8.4.3.2 The receiver shall compute and apply ionospheric corrections.

Note - Two methods of computing ionospheric corrections are provided in 3.1.2.4 and 3.5.5.5.2.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 151

3.5.8.4.3.3 The receiver shall apply a tropospheric model such that residual pseudo-range errors have a mean value (μ) less than 0.15 meters and a standard deviation less than 0.07 meters.

Note - A model was developed that meets this requirement. Guidance is provided in Attachment D, 6.5.4.

3.5.8.4.3.4 The receiver shall compute and apply horizontal and vertical protection levels as defined in 3.5.5.6. In this computation, σ_{tropo} shall be obtained either from the formula in 3.5.8.4.2.5, which can be used for elevation angles not less than 4 degrees, or from the alternate formula below, which can be used for elevation angles not less than 2 degrees:

$$\frac{1.001}{\sqrt{0.002001 + \sin^2(\theta_i)}} \times (1 + 0.015 \times (\max(0, 4 - \theta_i))^2) \times 0.12 \text{ m}$$

where θ_i is the elevation angle of the i^{th} satellite.

In addition, $\sigma_{i,\text{air}}$ shall satisfy the condition that a normal distribution with zero mean and standard deviation equal to $\sigma_{i,\text{air}}$ bounds the error distribution for residual aircraft pseudo-range errors as follows:

$$\int_y^{\infty} f_i(x) dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \frac{y}{\sigma} \geq 0 \text{ and}$$

$$\int_{-\infty}^{-y} f_i(x) dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \frac{y}{\sigma} \geq 0$$

where

$f_i(x)$ = probability density function of the residual aircraft pseudo-range error and

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} e^{-\frac{t^2}{2}} dt$$

Note - The standard allowance for airborne multipath defined in 3.6.5.5.1 may be used to bound the multipath errors.

3.5.8.4.4 For departure, en-route, terminal, and non-precision approach operations, the receiver should use the broadcast ionospheric corrections, when available, and a tropospheric model with performance equal to that specified in 3.5.8.4.3.

3.5.9 SBAS L5 RF Characteristics

3.5.9.1 *Carrier frequency stability.* The short-term stability of the L5 carrier frequency (square root of the Allan variance) at the output of the satellite transmit antenna shall be better than 6.7×10^{-11} over 1 to 10 seconds.

3.5.9.2 *Carrier phase noise.* The phase noise spectral density of the unmodulated carrier shall be such that a phase locked loop of 10 Hz one-sided noise bandwidth is able to track the carrier to an accuracy of 0.1 radian (1 sigma).

3.5.9.3 *Spurious emissions.* Spurious emissions shall be at least 40 dB below the unmodulated carrier power over all frequencies.

3.5.9.4 Code/carrier frequency coherence

3.5.9.4.1 For L5, the rate of change of code minus carrier shall be less than 0.5 metres/second.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 152

3.5.9.4.2 For DFMC SBAS ranging satellites:

Note.— See 3.5.1.1 and 3.5.1.2 for a description of the smoothing filters to be used for the requirements below.

3.5.9.4.2.1 The root-mean-square (RMS) value over 3 600 seconds of the difference between the L5 code pseudo-range and the L5 code pseudo-range smoothed using a 10-second carrier smoothing of the code based pseudo-range shall be less than 0.200 metres.

3.5.9.4.2.2 The RMS value over 86 400 seconds of the difference between the L5 code pseudo-range and the L5 code pseudo-range smoothed using a 100-second carrier smoothing of the code based pseudo-range shall be less than 0.255 metres.

3.5.9.4.2.3 The RMS value over 3 600 seconds of the difference between the L1 code pseudo-range and the L1 code pseudo-range smoothed using a 10-second carrier smoothing of the code based pseudo-range shall be less than 0.15 metres.

3.5.9.4.2.4 The RMS value over 86 400 seconds of the difference between the L1 code pseudo-range and the L1 code pseudo-range smoothed using a 100-second carrier smoothing of the code based pseudo-range shall be less than 0.19 metres.

3.5.9.4.2.5 *L1 and L5 short-term fractional code/carrier frequency coherence.* For L1 and L5 signals broadcast by an SBAS ranging satellite, the RMS value over 3 600 seconds of the difference between the ionosphere-free pseudo-range and the ionosphere-free pseudo-range smoothed using a 10-second carrier smoothing of the L1/L5 ionosphere-free pseudo-range combination shall be less than 0.29 metres.

3.5.9.4.2.6 *L1 and L5 long-term fractional code/carrier frequency coherence.* For L1 and L5 signals broadcast by an SBAS ranging satellite, the RMS value over 86 400 seconds of the difference between the ionosphere-free pseudo-range and the ionosphere-free pseudo-range smoothed using a 100 seconds carrier smoothing of the L1/L5 ionosphere-free pseudo-range combination shall be less than 0.37 metres.

3.5.9.5 *Correlation loss.* The loss in the recovered signal power due to imperfections in the signal modulation and waveform distortion shall not exceed 1 dB.

Note.— The correlation loss is defined as the ratio of output powers from a perfect correlator for two cases:

- a) *the actual received SBAS L5 signal correlated against a perfect unfiltered pseudo-random noise reference; and*
- b) *a perfect unfiltered pseudo-random noise signal normalized to the same total power as the SBAS signal in case a), correlated against a perfect unfiltered pseudo-random noise reference.*

3.5.9.6 *Maximum code phase deviation.* The L5 broadcast signal shall not deviate from the equivalent SBAS network time (SNT) for DFMC SBAS by more than $\pm 2 \cdot 10^{-10}$ seconds.

3.5.9.7 *Code/data coherence.* Each 2-millisecond symbol shall be synchronous with every other code epoch.

3.5.9.8 *Message synchronization.* The leading edge of the first symbol that depends on the first bit of the current message shall be broadcast from the SBAS satellite synchronous with a 1-second epoch of SNT for DFMC SBAS.

Note.— The SNT time reference is provided by the Type 37 message as described in 3.5.11.5.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

3.5.9.9 Convolutional and bi-binary encoding

3.5.9.9.1 *Convolution encoding.* A 250-bit-per-second data stream shall be encoded at a rate of 2 symbols per bit using a convolutional code with a constraint length of 7 to yield 500 symbols per second. The convolutional encoder logic arrangement shall be as illustrated in Figure B-11 with the G3 output selected for the first half of each 4-millisecond data bit period.

3.5.9.9.2 *Bi-binary encoding.* In addition to the convolution coding detailed in paragraph 3.5.9.9.1, the convolution encoded 500 symbols per second data channel shall be further bi-binary encoded such that a “0” symbol becomes a “01” pair and a “1” symbol becomes a “10” pair resulting in a data channel operating at a 1 kHz rate.

Note.— See Attachment D, Section 6.4.4.

3.5.9.10 *Pseudo-random noise (PRN) codes for L5.* Each PRN code shall be a 10 230-bit code and be added Modulo-2 with the navigation message data stream generated in paragraph 3.5.9.9.2.

Note.— Additional information on the PRN code is given in IS-GPS-705F.

The initial state for the XA shift register shall be “111111111111”, and the initial state for the XBi register shall be as illustrated in Table B-97.

Table B-97. SBAS L5 PRN codes

<i>PRN code number</i>	<i>Initial XB code state (I channel) (Note 1)</i>	<i>XB code advance (chips) (I channel) (Note 2)</i>

3.5.10 Data Structure on SBAS L5 signal

Note.— Messages broadcast for use under DFMC SBAS service are independent from those broadcast for use under L1 SBAS service. Information broadcast on SBAS L5 signal is used only for DFMC SBAS service solutions using dual-frequency measurements from core constellations.

3.5.10.1 *Format summary.* All messages shall consist of a preamble, a message type identifier, a data field and a cyclic redundancy check as illustrated in Figure B-28.

3.5.10.2 *Preamble.* For L5, the preamble shall consist of the sequence of bits “0101 1100 0110 1001 0011 1010”, distributed over six successive blocks. The start of every 24-bit preamble shall be synchronous with SNT time of day in seconds Modulo 6 seconds.

3.5.10.3 *Message type identifier.* The L5 message type identifier shall be a 6-bit value identifying the message type as defined in Table B-98. The message type identifier shall be transmitted MSB first.

Table B-98. L5 broadcast message types

<i>L5 message type</i>	<i>Contents</i>
0	“Do Not Use” – content applies to DFMC SBAS service only
1-30	Spare
31	SBAS satellite mask
32	Satellite clock-ephemeris corrections and covariance matrix
33	Spare
34, 35, 36	Integrity information (DFREI and DFRECI)
37	Degradation parameters and DFREI scale table
38	Spare
39	SBAS satellite clock, ephemeris and covariance matrix - 1
40	SBAS satellite clock, ephemeris and covariance matrix - 2
41	Spare
42	SNT-to-UTC offset
43-46	Spare
47	SBAS satellites almanacs
48-61	Spare
62	Reserved – content applies to DFMC SBAS service only
63	Null message – content applies to DFMC SBAS service only

Note.— L1 messages (Table B-62) are for use with L1 SBAS service and L5 messages (Table B-98) are for use with DFMC SBAS service. Types 0, 62 and 63 messages are used independently by both L1 SBAS and DFMC SBAS services and their contents only apply to their service.

3.5.10.4 *Data field.* The L5 data field shall be 216 bits as defined in 3.5.13. Each data field parameter shall be transmitted MSB first.

3.5.10.5 *Cyclic redundancy check (CRC).* The SBAS message CRC code on L5 shall be calculated in accordance with 3.9.

3.5.10.5.1 The length of the CRC code shall be $k = 24$ bits.

3.5.10.5.2 The CRC generator polynomial shall be:

$$G(x) = x^{24} + x^{23} + x^{18} + x^{17} + x^{14} + x^{11} + x^{10} + x^7 + x^6 + x^5 + x^4 + x^3 + x + 1$$

3.5.10.5.3 The CRC information field, $M(x)$, shall be:

$$M(x) = \sum_{i=1} m_i x^{226-i} = m_1 x^{225} + m_2 x^{224} + \dots + m_{226} x^0$$

3.5.10.5.4 M(x) shall be formed from the 4-bit SBAS message preamble, 6-bit message type identifier, and 216-bit data field. Bits shall be arranged in the order transmitted from the SBAS satellite, such that m₁ corresponds to the first transmitted bit of the preamble, and m₂₂₆ corresponds to bit 216 of the data field.

3.5.10.5.5 The CRC code r-bits shall be ordered such that r₁ is the first bit transmitted and r₂₄ is the last bit transmitted.

3.5.11 DFMC SBAS Data Content

3.5.11.1 *Satellite mask parameters.* The satellite mask parameters shall be as follows:

SBAS satellite mask: the satellite mask shall be a set of 214 bits such that each bit represents one specific satellite as shown in Table B-99 and the value of that bit shall indicate whether augmentation is, or is not, provided for that satellite. It shall be broadcast in the Type 31 message.

Note.— The satellite mask can set up to 92 satellites from the 214 possible satellites available for augmentation.

Satellite slot number: a unique number representing a specific slot in the SBAS satellite mask (slots numbers range from 1 to 214) assigned to a specific satellite for which augmentation can be provided.

Note 1.— The first transmitted bit of the satellite mask corresponds to GPS PRN code number 1.

Note 2.— This parameter is also broadcast in Type 32 messages to identify the satellite to which the corrections apply.

Table B-99. Satellite slot number assignments

<i>Satellite slot number</i>	<i>Assignment logic</i>
1 – 32	GPS PRN
33 – 37	Reserved (GPS)
38 – 69	GLONASS ID number plus 37
70 – 74	Reserved (GLONASS)
75 – 110	Galileo space vehicle identifier plus 74
111	Reserved (Galileo)
112 – 119	Spare
120 – 158	GEO SBAS PRN
159 – 195	BDS ranging code number plus 158
196 – 207	Reserved
208 – 214	Spare

Note 1.— An SBAS may augment different sets of satellites for the provision of L1 SBAS service and for the provision of DFMC SBAS service.

Note 2.— Reserved means that the slot number has not yet been assigned but is planned for assignment to a specific satellite constellation.

SBAS augmented satellite signals: the DFMC SBAS standards shall allow the augmentation of the ionosphere-free combination of the following signal per core constellation:

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 157

- a) for GPS: the GPS L1 C/A signal (as described in Chapter 3, 3.7.3.1.1.8 and 3.1.1.1.1) and the GPS L5-Q signal (as described in Chapter 3, 3.7.3.1.8 and 3.1.1.1.4). The LNAV data on GPS L1C/A shall be used in DFMC SBAS position solution;
- b) for GLONASS: the GLONASS L1 OC signal (as described in Chapter 3, 3.7.3.1.2.10 and 3.1.2.1.5) and the GLONASS L3 OC signal (as described in Chapter 3, 3.7.3.1.2.9 and 3.1.2.1.5). The data on GLONASS L1 OC shall be used in DFMC SBAS position solution;
- c) for Galileo: the Galileo E1-C signal (as described in Chapter 3, 3.7.3.1.3.11 and 3.1.3.1.1.2) and the Galileo E5a-Q signal (as described in Chapter 3, 3.7.3.1.3.11 and 3.1.3.1.1.3). The FNAV data on Galileo E5a-I shall be used in DFMC SBAS position solution;
- d) for BDS: the BDS B1C signal (as described in Chapter 3, 3.7.3.1.4.9 and 3.1.4.1.1.3) and the BDS B2a signal (as described in Chapter 3, 3.7.3.1.4.10 and 3.1.4.1.1.4). The B-CNAV2 data on BDS B2a shall be used in DFMC SBAS position solution; and
- e) for SBAS: the SBAS L1 signal (as described in 3.5.2) and SBAS L5 signal (as described in 3.5.9). The data broadcast on SBAS L5 shall be used in DFMC SBAS position solution.

Satellite slot value: binary indication per satellite slot to indicate whether correction and integrity data are provided for the satellite.

Coding: 0 = data not provided
1 = data provided

Augmented slot index: a number in the sequence of the satellite slot values set to “1” (1 up to 92) in the SBAS satellite mask.

Note.— The augmented slot index is “1” for the lowest satellite slot number for which the satellite slot value is “1”.

Issue of data mask (IODM): an indicator provided in Types 31, 34, 35 and 36 messages that links the integrity data provided in Types 34, 35 and 36 messages with the augmented slot indexes in the Type 31 message with the same IODM.

3.5.11.2 Satellite clock-ephemeris corrections and covariance matrix parameters. The clock-ephemeris corrections and covariance matrix function parameters shall be as follows:

Satellite slot number: see 3.5.11.1.

Issue of data navigation (IODN): a 10-bit indicator broadcast in Type 32 messages that associates the clock and ephemeris corrections of a satellite with the ephemeris data broadcast by that satellite. The IODN for a given satellite matches with the following information (IODs) broadcast by the same satellite:

- a) for GPS: IODC parameter (3.1.1.1.3.1.4) in the L1 LNAV message;
- b) for GLONASS: t_b parameter (3.1.2.1.3.1) in strings Type 10, 31, 32 of L1OC navigation message;
- c) for Galileo: IODnav parameter (3.1.3.1.3.7) in the F/NAV message;
- d) for BDS: IODC parameter (3.1.4.1.3.2.4.2) in the B-CNAV2 message; and
- e) for SBAS: IODG parameter (3.5.11.5) in the Type 39/40 messages.

Orbit and clock parameters corrections: The orbit parameters shall be defined as follows:

- $\delta x_{(ECEF)}$: ephemeris correction for the X-axis in WGS84 ECEF coordinates;
- $\delta y_{(ECEF)}$: ephemeris correction for the Y-axis in WGS84 ECEF coordinates;
- $\delta z_{(ECEF)}$: ephemeris correction for the Z-axis in WGS84 ECEF coordinates;
- $\delta B_{(ECEF)}$: clock offset error correction expressed in metres;
- $\delta \dot{x}_{(ECEF)}$: ephemeris velocity correction for the X-axis in WGS84 ECEF coordinates;
- $\delta \dot{y}_{(ECEF)}$: ephemeris velocity correction for the Y-axis in WGS84 ECEF coordinates;
- $\delta \dot{z}_{(ECEF)}$: ephemeris velocity correction for the Z-axis in WGS84 ECEF coordinates;
- $\delta \dot{B}_{(ECEF)}$: clock drift error correction expressed in metres per second; and

t_D : time of applicability of the parameters δx , δy , δz , δB , $\delta \dot{x}$, $\delta \dot{y}$, $\delta \dot{z}$ and $\delta \dot{B}$ expressed in seconds of the day (see Attachment D, 6.7.11).

Scale exponent: a term to compute the scale factor used to code the Cholesky factorization elements.

Cholesky factorization elements ($E_{i,j}$): elements of an upper triangle matrix which compresses the information in the clock and ephemeris covariance matrix. These elements are used to compute the user location factor (δ_{DFRE}) as a function of user position (see 3.5.12.4.1).

Dual-frequency range error indicator (DFREI): a 4-bit indicator of the dual-frequency range error (DFRE) value, with range from 0 to 15, with value 15 corresponding to “Do Not Use for SBAS”.

Note 1.— For other values (from 0 to 14), the table defining the correspondence between the DFREI values and the standard deviation (σ_{DFRE} , in metres) is given in 3.5.11.4.

Note 2.— The broadcast standard deviation values (within the allowed ranges as defined in 3.5.11.4) are SBAS-dependent.

δR_{CORR} : the first order degradation parameter multiplier.

Note.— All parameters are broadcast in the Type 32 message.

3.5.11.3 *Integrity message parameters.* The integrity message parameters shall consist of:

Dual-frequency range error change indicator (DFRECI): a 2-bit indicator that denotes the integrity status of a specific satellite identified by its augmented slot index (see 3.5.11.1), as specified in Table B-100.

Table B-100. DFRECI indicator

<i>DFRECI</i>	<i>State</i>
0 (“00”)	Unchanged DFREI
1 (“01”)	Changed DFREI
2 (“10”)	Active DFREI value increased by one
3 (“11”)	Do not use this satellite in SBAS mode
<p><i>Note.— For a given satellite, the DFRECI indication “00”, and “10” always refers to the last valid DFREI received (active DFREI) for that satellite. An active DFREI could be any broadcast DFREI that has not yet timed out. DFRECI “10” indications are not cumulative.</i></p>	

Issue of data mask (IODM): see 3.5.11.1.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 159

Dual-frequency range error indicator (DFREI): see 3.5.11.2.

Note.— Parameters are broadcast using one or more the following message types:

- a) Type 34 message providing DFRECI for all augmented satellites, DRFEI for up to 7 augmented satellites and IODM; and
- b) Types 35 and 36 messages broadcasting IODM and DFREIs for a maximum set of 53 and 39 augmented satellites, respectively.

3.5.11.4 *Degradation parameters and DFREI scale table parameters.* The old but active data (OBAD) parameters and DFREI scale table parameters shall be as follows:

Common OBAD parameters: a set of parameters common to all augmented satellites where

(IVALID)₃₂ is the Type 32 message validity interval;

(IVALID)_{39/40} is the Types 39 and 40 messages validity interval;

C_{ER} is the step degradation parameter for en-route through non-precision approach applications;

C_{COVARIANCE} is the clock-ephemeris covariance degradation parameter; and

Degradation equation selector indicates how the degradation terms combine for the dual-frequency residual error model variance.

Coding: 0 = δ_{DFRE} only multiplies σ_{DFRE} , correction residuals are root-sum squared

1 = δ_{DFRE} multiplies the linear sum of σ_{DFRE} and the degradation parameters

Specific OBAD parameter: a set of parameters linked to a given core constellation used to account for the degradation of corrections that are old but still valid, where:

I_{CORR} is the time interval for application of C_{CORR};

C_{CORR} is the step degradation parameter for precision approach applications; and

R_{CORR} is the first order degradation parameter.

Time reference identifier: a parameter that specifies the GNSS constellation on which the SNT for DFMC SBAS is aligned, where

“0” is GPS;

“1” is GLONASS;

“2” is Galileo;

“3” is BDS;

“4” is reserved; and

“5”, “6” and “7” are spare.

DFREI scale table: provides the mapping between the DFREI parameter (see 3.5.11.2) and σ_{DFRE} as specified in Table B-101.

σ_{DFRE} is the standard deviation of the residual ionosphere-free clock and ephemeris range error following the application of the DFMC SBAS clock and ephemeris corrections (Type 32 message) or of the SBAS satellite clock and ephemeris (Type 39/40 message).

Table B-101. Evaluation of σ_{DFRE} in metres

Field value _{dec}	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

σ_{DFRE} : DFREI=15	DO NOT USE THIS SATELLITE IN SBAS MODE															

Note.— All parameters are broadcast in the Type 37 message.

3.5.11.5 SBAS satellite clock, ephemeris and covariance matrix parameters. The broadcasting SBAS satellite clock, ephemeris and covariance data shall be as follows:

Issue of data GEO (IODG): an issue of data indicator that links Type 39 and 40 messages.

Note.— Each message of a paired Type 39/40 message set contains the same 2-bit IODG.

SBAS service provider ID: identifies the SBAS service provider responsible for the signal broadcast by the SBAS satellite, as defined in Table B-27.

Keplerian parameters: the ephemeris information to determine the ionosphere-free dual-frequency L1/L5 antenna phase centre location is:

- Cuc is the amplitude of cosine harmonic correction terms to the argument of latitude;
- Cus is the amplitude of sine harmonic correction terms to the argument of latitude;
- Idot is the rate of inclination angle;
- a is the semi-major axis;
- ω is the argument of perigee;
- Ω_0 is longitude of ascending node of orbital plane at t_e ;
- M0 is the mean anomaly at t_e ;
- I is the inclination at t_e ; and
- e is the eccentricity;

Satellite slot delta: identifies the broadcasting SBAS satellite in Table B-102.

Note.— A satellite slot delta of 0 is used in the Type 47 message to indicate that no almanac data follows.

Table B-102. Satellite slot delta assignments

<i>Satellite slot delta</i>	<i>Assignment logic</i>
0	No SBAS satellite (coding only used in Type 47 messages)
1 – 39	SBAS GEO satellite PRNs 120-158
40 – 63	Spare

SBAS ephemeris time t_e : time of applicability of the ephemeris message in seconds of day;
clock parameters: provided for ionosphere-free position as follows:

agf0: clock offset; and
agf1: clock rate;
scale exponent: see 3.5.11.2;
covariance matrix: see 3.5.11.2;
dual-frequency range error indicator (DFREI): see 3.5.11.2; and
 δR_{CORR} : see 3.5.11.2.

Note.— All parameters are broadcast in combined Type 39 and Type 40 messages.

3.5.11.6 *GNSS time offsets parameters*. The GNSS time parameters shall be as follows:

The common UTC parameters are:

A_{ISNT} : drift coefficient of the SNT scale for DFMC SBAS relative to UTC;
 A_{OSNT} : bias coefficient of the SNT scale for DFMC SBAS relative to UTC time scale;
 t_0t : time data reference time of week;
 WN_t : data reference week number;
 Δt_{LS} : current or past leap second count;
 WN_{LSF} : leap second reference week number;
 DN : leap second reference day number;
 Δt_{LSF} : current or future leap second count; and
 UTC standard identifier (defined in 3.5.4.8).

The validity model parameters of the SNT-to-UTC offset model are:

TOW_{app} : start time in time of week of the validity period of the information broadcast in the common UTC parameter field;

WN_{app} : week number associated to the TOW_{app} defining the validity period of the information broadcast in the common UTC parameter field. WN_{app} set to 0 means that the $WN_{app} = WN_t - 1$. WN_{app} set to 1 means that the $WN_{app} = WN_t$;

VP : identifies the validity period (time-out) duration according to Table B-116 for the common UTC information; and UTC offset status: SNT-to-UTC offset validity status defined according to Table B-103.

Table B–103. UTC offset status parameter

<i>UTC offset status</i>	<i>State</i>
0	Previously received common UTC information remains valid, no change in validity period.
1	Previously received common UTC information is no longer valid and shall no longer be used.

Table B–104. VP parameter

<i>VP</i>	<i>VP duration</i>	<i>VP</i>	<i>VP duration</i>
0 (“000”)	1 day from broadcast	4 (“100”)	6 hours
1 (“001”)	1 hour	5 (“101”)	9 hours
2 (“010”)	2 hours	6 (“110”)	12 hours
3 (“011”)	4 hours	7 (“111”)	24 hours

The time-out for the SNT-to-UTC offset information (noted TO₄₂ below) shall be defined as follows:

- a) if VP is set to 0: TO₄₂ = Type 42 message received time + 86 400 s;
- b) if VP is set to a value different from 0: TO₄₂ = start time in seconds (defined by TOW_{app} and WN_{app}) + (VP duration) × 3 600.

Note 1.— All parameters are broadcast in a Type 42 message.

Note 2.— It is not intended that Type 42 messages be used for positioning services with integrity, as no integrity budget is defined in SBAS system for the time offset parameters.

3.5.11.7 SBAS satellite parameters. The SBAS satellite parameters shall be as follows:

satellite slot delta: see 3.5.11.5;

SBAS service provider ID: see 3.5.11.5;

broadcast indicator: when set to 1, it identifies the almanac data of the broadcasting satellite. It shall be set to 0 otherwise;

almanac parameters: broadcast using Keplerian parameters, where:

a is the semi-major axis;

e is the eccentricity;

I is the inclination;

ω is the argument of perigee;

Ω₀ is the longitude of ascending node of orbital plane at beginning of week;

Ω is the rate of right ascension of the ascending node;

M₀ is the mean anomaly at t_a; and

t_a is SBAS almanac time (the almanac reference epoch in seconds of day);

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 163

week number rollover count (WNRO_{count}): the number of week number rollovers already elapsed for the GNSS constellation identified by the time reference identifier at the almanac reference time, t_a , broadcast in the SBAS I Keplerian parameters block of the Type 47 message (see Table B-104). WNRO_{count} value of 15 shall be used to indicate that the parameter is not valid and will be updated. The starting time per constellation with respect to UTC shall be:

- a) for GPS: midnight between 5 January 1980 and 6 January 1980 (see 3.1.1.4);
- b) for GLONASS: midnight between 31 December 1995 and 1 January 1996 (see 3.1.2.4);
- c) for Galileo: 13 seconds before midnight between 21 August 1999 and 22 August 1999 (see 3.1.3.4); and
- d) for BDS: midnight between 31 December 2005 and 1 January 2006 (see 3.1.4.4).

Note 1.— All parameters are broadcast in a Type 47 message.

Note 2.— The Type 47 message provides the capacity to transmit the SBAS almanacs parameters of 2 SBAS satellites.

3.5.12 Definitions of protocols for DFMC SBAS data applications

Note.— This section provides the definitions of parameters used by SBAS (non-aircraft and aircraft elements) that are needed to compute the navigation solution and associated integrity (protection levels).

3.5.12.1 General information for DFMC SBAS data protocol

The conventional values to be used for the computation of the earth-fixed coordinates of the SBAS space vehicle antenna phase centre shall be:

$\pi = 3.1415926535898$ (ratio of a circle's circumference to its diameter);

$\mu = 3.986005 \times 10^{14} \text{ m}^3/\text{s}^2$ (earth's gravitational parameter);

$\Omega_e = 7.2921151467 \times 10^{-5} \text{ rad/s}$ (earth's rotation rate); and

$c = 299\,792\,458 \text{ m/s}$ (speed of light in a vacuum).

Note.— The values of these parameters are not broadcast by SBAS but use of the correct values is necessary to ensure interoperability between different SBAS implementations.

When computing a time difference ($t-t_0$) where the reference time t_0 is expressed in the SNT (such as t_D broadcast in Type 32 message, t_e broadcast in Type 40, t_a broadcast in Type 47 message), the time t used in 3.5.12 shall be expressed in the same time frame considering the conversion elements in Table B-105.

Table B-105. Conversion from a core constellation reference time to the SNT

		“0”	“1”	“2”	“3”
Core constellation reference time	GPS	$t^{(SNT=0)} = t^{(GPST)}$	$t^{(SNT=1)} = t^{(GPST)} - \Delta tLS + 10\,800\text{ s}$	$t^{(SNT=2)} = t^{(GPST)}$	$t^{(SNT=3)} = t^{(GPST)} - 14\text{ s}$
	GLONASS	$t^{(SNT=0)} = t^{(GLONASST)} + \Delta tLS - 10\,800\text{ s}$	$t^{(SNT=1)} = t^{(GLONASST)}$	$t^{(SNT=2)} = t^{(GLONASST)} + \Delta tLS - 10\,800\text{ s}$	$t^{(SNT=3)} = t^{(GLONASST)} + \Delta tLS - 10\,800\text{ s}$
	Galileo	$t^{(SNT=0)} = t^{(GST)}$	$t^{(SNT=1)} = t^{(GST)} - \Delta tLS + 10\,800\text{ s}$	$t^{(SNT=2)} = t^{(GST)}$	$t^{(SNT=3)} = t^{(GST)} - 14\text{ s}$
	BDS	$t^{(SNT=0)} = t^{(BDT)} + 14\text{ s}$	$t^{(SNT=1)} = t^{(BDT)} - \Delta tLS + 10\,800\text{ s}$	$t^{(SNT=2)} = t^{(BDT)} + 14\text{ s}$	$t^{(SNT=3)} = t^{(BDT)}$
<p><i>Note 1.— ΔtLS is computed through core constellation information.</i></p> <p><i>Note 2.— Table B-105 describes how to convert a time of day $t^{(GNSS)}$ expressed in one of the GNSS core constellation reference times into time of day $t^{(SNT=i)}$ expressed in the SNT specified by the time reference identifier i.</i></p>					

3.5.12.2 Determination of SBAS satellite position based on its almanac.

The following parameters described in 3.5.11.7 shall be used in the computation of the SBAS satellite position based on its almanac:

- t_a : SBAS almanac time (the reference epoch of the almanac (s) as a time of day);
- a : semi-major axis (m);
- e : eccentricity (dimensionless);
- M_0 : mean anomaly (rad) at t_a ;
- ω : argument of perigee (rad);
- I : inclination angle (rad);
- Ω_0 : longitude of ascending node of orbital plane at beginning of week (rad); and
- $\dot{\Omega}$: rate of right ascension of the ascending node (rad/s).

The computation of the SBAS satellite position shall be made for the epoch t , expressed in the SNT frame for DFMC SBAS. The “almanac reference epoch” shall be broadcast as a time of day through t_a . The SBAS users shall account for the truncated nature of the t_a parameter.

3.5.12.2.1 Computation of the mean anomaly (M_t)

The mean anomaly (M_t) at the epoch t shall be computed as:

$$M_t = M_0 + n_0 \Delta t$$

where

$$n_0 = \sqrt{\frac{\mu}{a^3}}$$

$$\Delta t = t - t_a$$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 165

Note.— The SBAS user needs to ensure that t and t_a have the same time reference when computing Δt . Since the broadcast parameter t_a is a time of day, conversion is needed to account for day or week changes.

3.5.12.2.2 Computation of the eccentric anomaly (E_t)

The eccentric anomaly (E_t) for epoch t shall be computed solving the equation:

$$M_t = E_t - e \sin(E_t)$$

Note.— This equation may be solved by iteration.

3.5.12.2.3 Computation of the argument of latitude (Φ_t)

The argument of latitude (Φ_t) for epoch t shall be computed as:

$$\phi_t = v_t + \omega$$

where v_t is the true anomaly at epoch t :

$$v_t = 2 \times \operatorname{atan} \left(\sqrt{\frac{1+e}{1-e}} \tan\left(\frac{E_t}{2}\right) \right)$$

3.5.12.2.4 Computation of the coordinates in the orbital plane ($x_t'; y_t'$)

The coordinates in the orbital plane ($x_t'; y_t'$) for epoch t shall be computed as:

$$x_t' = r_t \cos \phi_t$$

$$y_t' = r_t \sin \phi_t$$

where r_t is the orbit radius at epoch t : $r_t = a \times [1 - (e \times \cos E_t)]$

3.5.12.2.5 Computation of the space vehicle fixed earth's coordinates ($x_t; y_t; z_t$)

The space vehicle fixed earth's coordinates ($x_t; y_t; z_t$) for epoch t shall be computed as:

$$x_t = (x_t' \cos \Omega_t) - (y_t' \cos I \sin \Omega_t)$$

$$y_t = (x_t' \sin \Omega_t) - (y_t' \cos I \cos \Omega_t)$$

$$z_t = y_t' \sin I$$

where Ω_t is the corrected longitude of the ascending node at epoch t :

$$\Omega_t = \Omega_0 + [(\dot{\Omega} - \dot{\Omega}_e) \Delta t] - (\dot{\Omega}_e t_{aTOW})$$

and t_{aTOW} is t_a expressed in seconds as a time of week (or elapsed time since the beginning of the almanac week).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 166

3.5.12.3 Determination of SBAS satellite position based on its ephemeris

The following parameters, described in 3.5.11.5, shall be used in the computation of the SBAS satellite position based on its ephemeris:

- t_e : SBAS ephemeris time (the reference epoch of the ephemeris (s) as a time of day);
- a : semi-major axis (m);
- e : eccentricity (dimensionless);
- M_0 : mean anomaly (rad) at t_e ;
- ω : argument of perigee (rad);
- I : inclination angle at t_e (rad);
- \dot{I} : rate of inclination angle (rad/s);
- Ω_0 : longitude of the ascending node of orbital plane at t_e (rad);
- Cuc : amplitude of the cosine harmonic correction to the argument of latitude (rad); and
- Cus : amplitude of the sine harmonic correction to the argument of latitude (rad).

The computation of the SBAS satellite position shall be made for the epoch t , expressed in the SNT frame for DFMC SBAS. The “ephemeris reference epoch” shall be broadcast as a time of day through t_e . The SBAS users shall account for the truncated nature of the t_e parameter.

3.5.12.3.1 Computation of the mean anomaly (M_t)

The mean anomaly (M_t) at the epoch t shall be computed as:

$$M_t = M_0 + n_0 \Delta_t$$

where

$$n_0 = \sqrt{\frac{\mu}{a^3}}$$

$$\Delta_t = t - t_e$$

Note.— The SBAS user needs to ensure that t and t_e have the same time reference when computing Δ_t . Since the broadcast parameter t_e is a time of day, a conversion is needed to account for day or week changes.

3.5.12.3.2 Computation of the eccentric anomaly (E_t)

The eccentric anomaly (E_t) for epoch t shall be computed solving the equation:

$$M_t = E_t - e \sin(E_t)$$

Note.— This equation may be solved by iteration.

3.5.12.3.3 Computation of the argument of latitude (Φ_t)

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 167

The eccentric anomaly (Φ_t) for epoch t shall be computed as:

$$\phi_t = v_t + \omega$$

where v_t is the true anomaly at epoch t:

$$v_t = 2 \times \text{atan} \left(\sqrt{\frac{1+e}{1-e}} \tan\left(\frac{E_t}{2}\right) \right)$$

3.5.12.3.4 Computation of the corrected argument of latitude (u_t)

The corrected argument of latitude (u_t) for epoch t shall be computed as:

$$u_t = \phi_t + \delta u_t$$

where δu_t is the argument of latitude second harmonic perturbation at epoch t:

$$\delta u_t = [C_{us} \sin(2\phi_t)] + [C_{us} \cos(2\phi_t)]$$

3.5.12.3.5 Computation of the coordinates in the orbital plane (x'_t ; y'_t)

The coordinates in the orbital plane (x'_t ; y'_t) for epoch t shall be computed as:

$$\begin{aligned} x'_t &= r_t \cos u_t \\ y'_t &= r_t \sin u_t \end{aligned}$$

where r_t is the orbit radius at epoch t:

$$r_t = a[1 - (e \cos E_t)]$$

3.5.12.3.6 Computation of the space vehicle fixed earth's coordinates (x_t ; y_t ; z_t)

The space vehicle fixed earth's coordinates (x_t ; y_t ; z_t) for epoch t shall be computed as:

$$\begin{aligned} x_t &= (x'_t \cos \Omega_t) - (y'_t \cos i_t \sin \Omega_t) \\ y_t &= (x'_t \sin \Omega_t) + (y'_t \cos i_t \cos \Omega_t) \\ z_t &= y'_t \sin i_t \end{aligned}$$

where Ω_t is the corrected longitude of the ascending node at epoch t:

$$\Omega_t = \Omega_0 - (\dot{\Omega}_e \Delta t)$$

and i_t is the corrected inclination for epoch t:

$$i_t = I + (I_{\dot{I}} \Delta t)$$

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 168

Note 1.— The Sagnac correction (earth's rotation) needs to be taken into account.

Note 2.— The rate of right ascension of the ascending node is assumed to be zero.

3.5.12.4 SBAS DFMC navigation solution

Note - 3.5.12.4 provides formulas for the SBAS DFMC navigation solution of an SBAS system augmenting two core constellations, Constellation 1 (C1) and Constellation 2 (C2). When the number N of constellations being augmented is different from 2 ($N=1, 3$ or 4), the size of G and of X will need to vary accordingly. Additional information is available in Attachment D, 6.7.12.

The weighted least square navigation solution takes the following form:

$$\hat{X} = (G^T \cdot W \cdot G)^{-1} \cdot G^T \cdot W \cdot Y$$

- a) \hat{X} is the weighted least square estimate of the error in the estimated location of the user about which the linearization has been made:

$$X = [x, y, z, ct_{C1}, ct_{C1-C2}]$$

where

ct_{C1} is the clock bias of the receiver in seconds with respect to Constellation 1 reference time; and

ct_{C1-C2} is the time difference observed by the receiver in seconds between the reference constellation 2 and the constellation 1, namely $ct_{C1-C2} = t_{C2} - t_{C1}$;

Note.— This is one possible implementation. A second implementation is described in Attachment D, 6.7.12.

- b) Y is the P -dimensional vector containing the corrected ionosphere-free pseudo-range measurements $PR_{i,corrected}$, minus the expected ranging values based on the location of the satellites and the estimated location of the user (X), where

P is the number of satellites used in the navigation solution;

$PR_{i,corrected}$ is the corrected ionosphere-free pseudo-range measurement for the satellite i computed as specified in 3.5.1.2 with the parameters as follows:

b_i , defined in 3.5.1.2, is SBAS corrected clock:

$$b_i = c * (\delta\Delta t_{SV,i} + \Delta t_{SV,i});$$

$\delta\Delta t_{SV,i}$ is the time error estimate at time t computed with the parameters described in 3.5.11.2 as follows:

$$c * \delta\Delta t_{SV,i} = \delta B + \delta \dot{B}(t - t_D);$$

$\Delta t_{SV,i}$ is the satellite time correction described in 3.5.15.1.1.2; and

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 169

t_D is the reference time of the corrections.

The satellite position error correction vector $[\delta x(t), \delta y(t), \delta z(t)]$ shall be expressed in the WGS-84 ECEF coordinate frame as follows and shall be added to the satellite coordinate vector $[x(t), y(t), z(t)]$:

$$\begin{bmatrix} \delta x(t) \\ \delta y(t) \\ \delta z(t) \end{bmatrix} = \begin{bmatrix} \delta x \\ \delta y \\ \delta z \end{bmatrix} + \begin{bmatrix} \delta \dot{x} \\ \delta \dot{y} \\ \delta \dot{z} \end{bmatrix} (t - t_D)$$

with δx , δy , δz , $\delta \dot{x}$, $\delta \dot{y}$ and $\delta \dot{z}$ defined in 3.5.11.2.

Note 1.— The SBAS user needs to ensure that t and t_D have the same time reference when computing $t - t_D$. Since the broadcast parameter t_D is a time of day, a conversion is needed to account for day or week changes.

Note 2.— In case of SBAS ranging, for the SBAS ionosphere-free measurements of the SBAS providing the correction and integrity information, the time error estimate $\delta \Delta t_{sv}$ is zero as there is no correction provided for this satellite.

c) G is the observation matrix:

$$G_i = [-\cos E_{i_1} \cdot \sin A_{z_i} - \cos E_{i_1} \cdot \cos A_{z_i} - \sin E_{i_1} \quad 1 \quad n_i] = i^{\text{th}} \text{ row of } G$$

where

E_{i_1} is the elevation for satellite i after correction of its position using the parameters described in 3.5.11.2;

A_{z_i} is the azimuth for satellite i after correction of its position using the parameters transmitted described in 3.5.11.2. The positive azimuth is defined clockwise from North; and

n_i is “1” if satellite is part of reference constellation C2 or “0” if it is part of C1.

For SBAS ranging satellite: n_i is “0” if C1 is GPS and n_i is “1” if C2 is GPS.

Note 1.— The DFMC SBAS standards have no provisions for the augmentation of DFMC SBAS ranging signals from other service providers.

Note 2.— If SBAS ranging is provided by the SBAS and if the SBAS is not augmenting GPS, the SBAS range time offset needs to be solved by introducing an additional unknown in the observation matrix as explained in Attachment D, 6.7.12.1.

d) W is the weighting matrix:

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 170

$$W = \begin{bmatrix} w_1 & 0 & \dots & 0 \\ 0 & w_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & w_o \end{bmatrix}$$

where

$$w_i = 1/\sigma_i^2;$$

$$\sigma_i^2 = \sigma_{i,DFC}^2 + \sigma_{i,tropo}^2 + \sigma_{i,air_DF}^2 + \sigma_{i,iono}^2;$$

$\sigma_{i,DFC}^2$ is the model variance for the residual error associated to SBAS corrections for satellite i, as defined in 3.5.12.4.1;

$\sigma_{i,tropo}^2$ is the model variance for the troposphere residual error for satellite i, as defined in 3.5.8.4.2.4 and 3.5.8.4.2.5;

σ_{i,air_DF}^2 is the model variation for the combined measurement noise and multipath residual errors applicable to the ionosphere-free combination of dual-frequency range measurements (see 3.5.15.3.4.1) for satellite i; and

$\sigma_{i,iono}^2$ is the model variance for the ionosphere-free residual error for satellite i, as defined in 3.5.15.3.4.2.

3.5.12.4.1 Computation of the model variance for the residual error associated to SBAS corrections σ_{DFC}^2 .

Note.— The following calculations are done for each satellite. For convenience, the index i used in 3.5.12.4 was removed from the equations.

The user location factor (δ_{DFRE}) shall be obtained via the clock-ephemeris covariance matrix C as follows:

$$C=R^T R$$

where

$$R = 2^{(\text{scale exponent}-5)} = \begin{bmatrix} E_{1,1} & E_{1,2} & E_{1,3} & E_{1,4} \\ 0 & E_{2,2} & E_{2,3} & E_{2,4} \\ 0 & 0 & E_{3,3} & E_{3,4} \\ 0 & 0 & 0 & E_{4,4} \end{bmatrix}$$

then

$$\delta_{DFRE} = \sqrt{I^T C I} + \varepsilon_C$$

where

I is the 4-D line of sight vector from the user to the satellite in the WGS-84 coordinate frame where the first three components are the unit vector from the user to the satellite and the fourth component is 1;

ε_C is derived from $C_{\text{COVARIANCE}}$ (defined in 3.5.11.4) as:

$$\varepsilon_C = C_{\text{COVARIANCE}} \times 2^{\text{scale exponent}-5}; \text{ and}$$

scale exponent is defined in 3.5.11.2 and is transmitted through Type 32 messages for core constellation satellites and Type 40 messages for SBAS satellites.

The model variance for the residual error associated to SBAS corrections (σ_{DFC}^2) at the time t shall be computed using the SBAS corrections parameters described in 3.5.11.2 (for core constellations satellites) and 3.5.11.5 (for SBAS satellite) associated to the OBAD parameters described in 3.5.11.4 based on the broadcast degradation equation selector as follows:

$$\begin{aligned} \text{"0": } \sigma_{DFC}^2 &= \sigma_{DFRE}^2 \times \delta_{DFRE}^2 + \varepsilon_{CORR}^2 + \varepsilon_{ER}^2 \\ \text{"1": } \sigma_{DFC}^2 &= (\sigma_{DFRE}^2 + \varepsilon_{CORR}^2 + \varepsilon_{ER}^2)^2 \times \delta_{DFRE}^2 \end{aligned}$$

where

$$\varepsilon_{\text{CORR}} = \left\lfloor \frac{t - t_{\text{CORR}}}{I_{\text{CORR}}} \right\rfloor C_{\text{CORR}} + (t - t_{\text{CORR}}) \frac{(R_{\text{CORR}})_{\text{SV}}}{1000};$$

σ_{DFRE} is the standard deviation of the residual ionosphere-free clock and ephemeris range error as defined in 3.5.11.4;

$\varepsilon_{\text{CORR}}$ is the degradation parameter for corrections;

ε_{er} is the degradation parameter for en-route through non-precision approach applications. It shall be equal to 0 if the corrections have not timed out for approach applications (APV-I or Category I). It shall be equal to C_{er} (see 3.5.11.4) if any of the corrections or the DFREI/DFRECI (i.e. information broadcast in a valid Types 32, 34, 35, 36, 39 and 40 messages) have timed out for approach application but are still valid for en-route through non-precision approach applications;

t_{CORR} is the time of applicability (the start of the epoch of the SNT second that is coincident with the transmission by SBAS of the first bit of the message block) of the latest satellite or SBAS clock-ephemeris correction information received mapping with the satellite ephemeris;

I_{CORR} is the time interval for application of C_{CORR} (see 3.5.11.4);

C_{CORR} is the step degradation parameter for precision approach applications (see 3.5.11.4);

$(R_{\text{CORR}})_{\text{SV}}$ is the satellite specific degradation factor computed from R_{CORR} (see 3.5.11.4) and δR_{CORR} as in 3.5.11.2 (for the augmented satellites) or in 3.5.11.5 (for SBAS):

$$\text{if } t - t_{\text{CORR}} \leq I_{\text{CORR}}, \text{ then } (R_{\text{CORR}})_{\text{SV}} = R_{\text{CORR}} \times \delta R_{\text{CORR}}$$

$$\text{if } t - t_{\text{CORR}} > I_{\text{CORR}}, \text{ then } (R_{\text{CORR}})_{\text{SV}} = R_{\text{CORR}}; \text{ and}$$

$\lfloor x \rfloor$ is the greatest integer less than or equal to x .

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 172

3.5.12.5 Protection level calculation

For a general least-squares position solution, the projection matrix S shall be defined as:

$$S = \begin{bmatrix} S_{east,1} & S_{east,2} & \cdots & S_{east,P} \\ S_{north,1} & S_{north,2} & \cdots & S_{north,P} \\ S_{U,1} & S_{U,2} & \cdots & S_{U,P} \\ S_{t_{C_1},1} & S_{t_{C_1},2} & \cdots & S_{t_{C_1},P} \\ S_{t_{C_1}C_2,1} & S_{t_{C_1}C_2,2} & \cdots & S_{t_{C_1}C_2,P} \end{bmatrix} = (G^T \cdot W \cdot G)^{-1} \cdot G^T \cdot W$$

where

G is the observation matrix defined in 3.5.12.4; and

W is the weighting matrix defined in 3.5.12.4.

The horizontal protection level (HPL) and the vertical protection level (VPL) shall be computed as follows:

$$\begin{aligned} HPL &= K_H d_{major} \\ VPL &= K_{V,PA} d_U \end{aligned}$$

where

$$K_H = \begin{cases} 6.18 & \text{for en route through non precision approach operations;} \\ 6.0 & \text{for APV - I and Category I operations} \end{cases};$$

$$K_{V,PA} = 5.33;$$

d_{major} is the error uncertainty along the semi-major axis of the error ellipse defined as

$$d_{major} = \sqrt{\frac{d_{east}^2 + d_{north}^2}{2}} + \sqrt{\left(\frac{d_{east}^2 - d_{north}^2}{2}\right)^2 + d_{EN}^2};$$

d_U is the variance of model distribution that overbounds the true error distribution in the vertical axis defined as:

$$d_U^2 = \sum_{i=1}^P s_{U,i}^2 \sigma_i^2;$$

where

d_{east}^2 is the variance of model distribution that overbounds the true error distribution in the east axis:

$$d_{east}^2 = \sum_{i=1}^P s_{east,i}^2 \sigma_i^2;$$

d_{north}^2 is the variance of model distribution that overbounds the true error distribution in the north axis:

$$d_{north}^2 = \sum_{i=1}^P s_{north,i}^2 \sigma_i^2;$$

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

d_{EN} is the covariance of model distribution in the east and north axis:

$$d_{EN} = \sum_{i=1}^P s_{east,i} s_{north,i} \sigma_i^2;$$

$s_{(east,i)}$ is the partial derivative of position error in the east direction with respect to the pseudo-range error on the i^{th} satellite;

$s_{(north,i)}$ is the partial derivative of position error in the north direction with respect to the pseudo-range error on the i^{th} satellite;

$s_{(U,i)}$ is the partial derivative of position error in the vertical direction with respect to the pseudo-range error on the i^{th} satellite; and

σ_i is defined in 3.5.12.4.

3.5.13 DFMC SBAS Message Table

Each SBAS message shall be coded in accordance with the corresponding message format defined in Tables B-94 through B-106. All signed parameters in these tables shall be represented in two's complement, with the sign bit occupying the MSB.

Note 1.— The value of every parameter contained in a DFMC message is computed as follows, considering that field_{value} is the decimal value of the binary number, after two's complement transformation if specified in the description column of the table:

- if the parameter is coded as two's complement: $parameter = field_{value} * scale_{factor}$; and
- if the parameter is not coded as two's complement: $parameter = offset + field_{value} * scale_{factor}$, where the offset being specified in the comment column if different from the effective range minimum.

Note 2.— Reserved bits in DFMC messages can take any value.

Table B-106. Type 0 “Do Not Use” message broadcast on L5

Section	Name	Length	Scale factor	Effective range		Unit	Comment
				min	max		
Reserved	Reserved	216	-	-	-	-	

Note 1.— This message is the equivalent of the L1 SBAS Type 0 message but with application for the messages broadcast on DFMC SBAS service only.

Note 2.— When this message is broadcast, it indicates that the signal does not support safety-of-life operation. SBAS may broadcast the data field of any message type in each Type 0 message.

Note 2.— All other parameters are defined in 3.5.11.7.

Table B-117. Reserved

Table B-118. Type 63 null message broadcast on L5

Section	Name	Length	Scale factor	Effective Range		Unit	Comment
				min	max		
Reserved	Reserved	216	-	-	-	-	

Note.— The null message is used as a filler message if no other message is available for broadcast for the one-second time slot.

Table B-119. L5 message data time-out intervals

Data	Associated message types	Maximum update interval	En-route, terminal, NPA time-out	Precision approach, APV time-out
“Do Not Use”	0	6 s	N/A	N/A
Satellite mask	31	120 s	600 s	600 s
DFREI or DFRECI	32	6 s	18 s	12 s
	34	6 s	18 s	12 s
	35	6 s	18 s	12 s
	36	6 s	18 s	12 s
	40	6 s	18 s	12 s
Satellite clock-ephemeris corrections and covariance matrix	32	0.5x(I _{Valid}) ³² s per corrected satellite	1.5x(I _{Valid}) ³²	(I _{Valid}) ³²
SBAS satellite clock, ephemeris and covariance matrix	39 40	0.5x(I _{Valid}) ^{39/40} s	1.5x(I _{Valid}) ^{39/40}	(I _{Valid}) ^{39/40}
Degradation parameters	37	120 s	600 s	600 s
DFREI scale table	37	120 s	600 s	600 s
Time reference identifier	37	120 s	600 s	600 s
SBAS service provider identifier	47	120 s	600 s	600 s
SNT-to-UTC offset	42	240 s	Note 3	Note 3

Note 1.— The time-out intervals are defined from the time of arrival at the receiver’s antenna port of the last bit of the message.
Note 2.— There is no time-out requirement for other parameters of the Type 47 message than those listed above.
Note 3.— The SNT-to-UTC offset information in the Type 42 message times out as defined in 3.5.11.6 taking into account the parameters WN_{app} , TOW_{app} and VP .

3.5.14 DFMC SBAS Non-aircraft elements

Note.— The parameters that are referred to in this section are defined in 3.5.11.

3.5.14.1 General

3.5.14.1.1 *Required data and broadcast intervals.* SBAS shall broadcast the data required for the supported functions described in Chapter 3, 3.7.3.4.2 as shown in Table B-120.

Note.— SBAS may broadcast null messages (Type 63 messages) in each time slot for which no other data are broadcast.

3.5.14.1.1.1 All data broadcast by SBAS, whether required or not for a particular function, shall meet the update requirements in Table B-120.

Table B-120. L5 data broadcast intervals and supported functions

<i>Data type</i>	<i>Maximum broadcast interval</i>	<i>DFMC SBAS Ranging</i>	<i>Ionosphere-free differential correction</i>	<i>Associated message types</i>
“Do Not Use”	6 s			0
Clock-ephemeris error corrections and covariance matrix data	$0.5x(I_{\text{Valid}})_{32}$ s per corrected satellite		R	32
SBAS satellite mask	120 s	R	R	31
Integrity information (DFREI and optionally DFRECT)	6 s	R	R	32, 34, 35, 36 and 40
SBAS satellite clock-ephemeris corrections and covariance matrix data	$0.5x(I_{\text{Valid}})_{39/40}$ s	R		39 and 40
OBAD, DFREI scale table and time reference identifier	120 s	R	R	37
SBAS almanac data, broadcast indicator and SBAS service provider ID parameters	120 s	R	R	47
SNT-to-UTC offset	240 s			42

Note 1.— “R” indicates that the data must be broadcast to support the function.
Note 2.— Integrity information includes DFRECI only if the Type 34 message is broadcast, otherwise it is limited to DFREI.

3.5.14.1.2 SBAS radio frequency monitoring. The SBAS shall monitor the SBAS satellite parameters shown in Table B-121 and take the indicated action.

Table B-121. SBAS L5 radio frequency monitoring

<i>Parameter</i>	<i>Reference</i>	<i>Alarm limit</i>	<i>Required action (Note 1)</i>
Signal power level	Chapter 3, 3.7.3.4.5.3 and 3.7.3.4.6.3	minimum specified power maximum specified power (Note 2)	Minimum: cease DFMC SBAS ranging function. Maximum: cease broadcast.
Modulation	Chapter 3, 3.7.3.4.5.5 and 3.7.3.4.6.5	Monitor for waveform distortion	Cease DFMC SBAS ranging function.
Carrier frequency stability	3.5.2.1 and 3.5.9.1	N/A (Note 3)	Cease DFMC SBAS ranging function unless σ^2_{DFRE} reflects error.
Code/frequency coherence	3.5.2.4 and 3.5.9.4.2	N/A (Note 3)	Cease DFMC SBAS ranging function unless σ^2_{DFRE} reflects error.
Maximum code phase deviation	3.5.2.6 and 3.5.9.6	N/A (Notes 2 and 3)	Cease DFMC SBAS ranging function unless σ^2_{DFRE} reflects error.

<i>Parameter</i>	<i>Reference</i>	<i>Alarm limit</i>	<i>Required action (Note 1)</i>
Convolutional and binary encoding	3.5.2.9 and 3.5.9.9	All transmit messages are erroneous	Cease broadcast.

Notes.—

1. *The monitoring parameters which require action to “cease DFMC SBAS ranging function” are required only for SBAS satellites providing DFMC SBAS ranging. Ceasing the ranging function is accomplished by broadcasting a DFREI of “Do Not Use for SBAS” for that SBAS satellite.*
2. *These parameters can be monitored by their impact on the received signal quality (C/N₀ impact), since that is the impact on the user.*
3. *Alarm limits are not specified because the induced error is acceptable, provided it is represented in the σ_{DFRE}^2 parameter. If the error cannot be represented, the ranging function must cease.*

3.5.14.1.3 “Do Not Use”. SBAS shall broadcast a “Do Not Use” message (Type 0 message) when necessary to inform users not to use the SBAS satellite broadcast data on L5 and dual-frequency ranging function.

3.5.14.1.4 *Doppler shift in SBAS satellite.* The Doppler shift in the SBAS satellite signal seen at any fixed location within the footprint for any satellite shall not exceed:

- a) ± 337 Hz for GEO satellite signal; and
- b) ± 7 kHz for non-GEO satellite signal.

3.5.14.1.5 *SBAS ephemeris parameters.* When broadcasting ephemeris parameters, each SBAS satellite shall broadcast ephemeris parameters for itself as defined in 3.5.11.5.

3.5.14.1.5.1 The SBAS service provider shall ensure that the SBAS ephemeris time parameter t_e in the Type 40 message is set within -43 200 s and +43 199 s of the broadcast time and adjusted for day crossovers.

Note.— t_e is encoded as a time of day and the applicable day/week complies with the [-43 200 s; +43 199 s] time window.

3.5.14.1.6 *Almanac data.* Each SBAS satellite shall broadcast almanac data as defined in 3.5.11.7 for all SBAS satellites of the same service provider.

Note.— *Additional information for certain SBAS orbits is given in Attachment D, 6.7.5.*

3.5.14.1.6.1 The error in the estimated position of the satellite derived from any Type 47 message broadcast within the previous 15 minutes, with respect to the true satellite position, shall not exceed 3 000 km.

3.5.14.1.6.2 The error in the predicted Doppler shift computed from the Type 47 message shall not exceed ± 337 Hz for a period of seven days after the broadcast of the Type 47 message.

Note.— *SBAS receivers can expect this almanac accuracy for seven days from reception of the almanac message. The receiver needs to account for day and week crossovers since the almanac reference time is only in seconds of day.*

3.5.14.1.6.3 If only one SBAS satellite almanac is provided in the Type 47 message, the bits from 118 to 225 assigned to the second SBAS satellite almanac shall be coded with “0”.

3.5.14.1.6.4 SBAS shall set the broadcast indicator to “1” for the SBAS satellite broadcasting the Type 47 message, and set the broadcast indicator to “0” for all other SBAS satellites.

3.5.14.1.6.5 SBAS service provider shall ensure the correctness of the SBAS service provider ID using the value allocated to the SBAS service provider as per Table B-27 in any Type 47 message.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 186

3.5.14.1.6.6 SBAS service provider shall ensure that the SBAS almanac time parameter t_a in the Type 47 message is set within $-43\,200$ s and $+43\,199$ s of the broadcast time and adjusted for day crossovers.

Note.— t_a is encoded as a time of day and the applicable day/week complies with the $[-43\,200$ s; $+43\,199$ s] time window.

3.5.14.2 *Ranging function.* If an SBAS provides a DFMC SBAS ranging function, it shall also comply with the requirements contained in this section.

3.5.14.2.1 Performance requirements

Note.— See Chapter 3, 3.7.3.4.3.

3.5.14.2.2 *Ranging function data.* SBAS shall broadcast the ephemeris parameters, covariance matrix and DFREI value only for the broadcasting SBAS satellite through Type 39 and Type 40 messages both linked by their IODG.

3.5.14.2.3 *Active IODG.* SBAS shall have no more than three active IODG. An active IODG corresponds to an IODG parameter broadcast in Types 39 or 40 messages, which have not timed out as per Table B-107.

3.5.14.3 *Ionosphere-free differential correction function.* If an SBAS provides an ionosphere-free differential correction function, it shall also comply with the requirements contained in this section.

3.5.14.3.1 Performance of the ionosphere-free differential correction.

3.5.14.3.1.1 For en-route, terminal and non-precision approach, given any valid combination of active data, the probability of a horizontal error exceeding the HPL (as defined in 3.5.12.5) for longer than eight consecutive seconds shall be less than 10^{-7} in any hour, assuming a user with zero latency.

3.5.14.3.1.2 Given any valid combination of active data, the probability of an out of tolerance condition (e.g. horizontal error exceeding the HPL or vertical error exceeding the VPL, as defined in 3.5.12.5), for longer than 5.2 consecutive seconds time-to-alert shall be less than 2×10^{-7} during any approach, assuming a user with zero latency.

3.5.14.3.1.3 When SBAS detects that the probability of error exceeding the protection level is above the integrity risk requirement for one of the SBAS operations, the resulting alert information (set DFRE to a larger value or to “Do Not Use for SBAS”), broadcast in Types 32, 34, 35, 36 or 40 messages, shall be repeated three times in a row after the initial notification of the alert condition for a total of four times in four seconds.

Note 1.— A Type 0 message can also be sent four times in a row to indicate an alert condition. See attachment D, 6.7.4 for additional guidance.

Note 2.— Active data is defined as data that has not timed out per 3.5.15.1.4.2. This requirement includes core satellite constellation(s) and SBAS failures.

Note 3.— Subsequent messages can be transmitted at the normal update rate.

3.5.14.3.2 *SBAS satellite mask and issue of data mask (IODM).* SBAS shall broadcast an SBAS satellite mask and IODM (Type 31 message). The satellite slot values shall indicate whether or not data are being provided for each GNSS satellite.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 187

3.5.14.3.2.1 SBAS shall change the IODM when there is a change in the SBAS satellite mask by increasing by 1 the IODM Modulo-4 from the latest transmitted value.

3.5.14.3.2.2 The IODM in Type 34, 35 and 36 messages shall equal the IODM broadcast in the satellite mask message (Type 31 message) used to designate the satellites for which data are provided in those messages.

3.5.14.3.2.3 SBAS shall have no more than two active IODMs. An active IODM corresponds to a satellite mask broadcast in a Type 31 message, which has not timed out as per Table B-107.

3.5.14.3.3 *Satellite corrections and covariance matrix data.*

3.5.14.3.3.1 Except for the broadcasting SBAS satellite, SBAS shall broadcast clock and ephemeris corrections and covariance matrix (Type 32 message) for any satellite in the SBAS satellite mask (i.e. with satellite slot value equal to “1”) when SBAS sets a DFREI between 0 and 14.

Note.— The Type 39/40 message from the broadcasting satellite does not require further correction and therefore SBAS broadcasting satellite will not send correction data for itself.

3.5.14.3.3.2 SBAS shall broadcast clock and ephemeris correction and covariance matrix data with an issue of data navigation (IODN) matching to the clock and ephemeris data from GNSS satellites being corrected (IODs). The IODN value shall be derived from the IODs of GNSS satellite clock and ephemeris data as described in 3.5.11.2.

3.5.14.3.3.3 In order to enable all SBAS users to acquire the new GNSS data upon transmission of new valid clock and ephemeris data from the GNSS satellites, the SBAS shall continue to broadcast corrections and covariance matrix with respect to the old clock and ephemeris data for a period of time of:

- a) 20 to 240 seconds for GPS;
- b) 150 to 320 seconds for GLONASS;
- c) 150 to 350 seconds for Galileo; and
- d) 120 to 300 seconds for BDS.

Note.— “Valid clock and ephemeris data” means that the information broadcast by the GNSS satellites is in line with its signal interface control document (ICD), performance standard and SARPs.

3.5.14.3.3.4 For any non-SBAS satellite, SBAS shall only broadcast a Type 32 message when SBAS has continuously monitored that satellite’s ephemeris and clock data for at least 300 seconds.

Note.— IOD is defined in 3.5.11.2 and includes a comparison of the GPS LNAV IODE with the 8 LSB of the GPS LNAV IODC. Ephemeris and clock data is derived from the core constellation navigation message being augmented by DFMC SBAS as mentioned in 3.5.11.1.

3.5.14.3.3.5 SBAS service provider shall ensure that the correction time of applicability parameter t_D in the Type 32 message is set within -43 200 s and +43 199 s of the broadcast time and adjusted for day crossovers

Note.— t_D is encoded as a time of day and the applicable day/week complies with the [-43 200 s; +43 199 s] time window.

3.5.14.3.4 *Integrity data.* For each satellite set in the SBAS satellite mask, SBAS shall broadcast DFREI information using DFREI or DFRECI parameters, covariance matrix, scale exponent and degradation parameters such that the integrity requirement in 3.5.14.3.1 is met. If the corrections exceed their coding range or if σ_{DFC2} (as described in 3.5.12.4.1) cannot be determined, SBAS shall indicate that the satellite is not appropriate for SBAS position (“Do Not Use for SBAS”).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 188

Note.— The SBAS receiver will apply the DFRECI to its current active DFREI which can be any active broadcast DFREI.

3.5.14.3.4.1 SBAS shall provide DFREI information, directly via DFREI parameter or indirectly via DFRECI parameter, allowing the computation of σ_{DFRE} (as defined in 3.5.11.4) for the satellite set in the satellite mask and monitored by SBAS using Types 34, 35 or 36 messages at least every six seconds.

3.5.14.3.4.1.1 When using a Type 34 message, the SBAS shall transmit at most seven DFRECI values set to “1”.

Note 1.— Instead of transmitting updated DFREI values in the Type 34 message, the SBAS can set some DFRECI values to “2” or “3” to change DFREIs on more than seven satellites and still use the Type 34 message. Types 35 or 36 message can also be used instead of Type 34 messages to provide more DFREI value updates.

Note 2.— The DFRECI values are in augmented slot index order derived from the Type 31 message with a matching IODM.

3.5.14.3.4.1.2 When using a Type 34 message with DFRECI set to “1”, the SBAS shall broadcast the new DFREI values in the order corresponding to the order of DFRECI set to “1” across the DFRECI field. The new DFREI value shall apply to the augmented slot index of the corresponding DFRECI value set to “1”.

3.5.14.3.4.2 SBAS shall set to “15” any DFREI value in the associated data field of Types 35 and 36 messages, which corresponds to satellite slot number not set in the mask.

3.5.14.3.4.2.1 When using a Type 34 message, SBAS shall set DFRECI value to “3” for DFRECI slots exceeding the maximum augmented slot index.

3.5.14.3.4.2.2 If in a given Type 34 message, the number N of DFRECI set to “1” is below seven, the last 7-N DFREI values of the Type 34 message shall be set to “15”.

3.5.14.3.4.3 When using a Type 34 message, SBAS shall transmit a DFRECI of “3” (“Do Not Use for SBAS”) instead of transmitting a DFRECI of “2” (“DFREI increased by one”) when the most recent active DFREI was set to “14” and the corresponding DFRE value is no longer adequate to ensure integrity as per 3.5.14.3.1.

3.5.14.3.4.4 SBAS shall send (I_{VALID})₃₂ and (I_{VALID})_{39/40} in the Type 37 messages corresponding to the time intervals during which the integrity data of Type 32 and Type 39/40 messages can be used.

Note.— These time intervals are measured from the time of arrival of the last bit of Type 32 or the last bit of the last message in the paired Type 39/40 messages being received at the antenna port of the SBAS receiver.

3.5.14.3.4.5 The integrity requirement in 3.5.14.3.1 shall apply throughout the update of parameters in a Type 37 message.

Note.— It is expected that change in the DFREI scale table will be a rare event in the lifetime of an SBAS.

3.5.14.3.4.5.1 For each DFREI, the σ_{DFRE} value shall always be greater than the σ_{DFRE} value specified for lower DFREI in the scale table in the Type 37 message.

3.5.14.3.5 *Old but active data (OBAD).* SBAS shall broadcast OBAD parameters (Type 37 message) such that the integrity requirement in 3.5.14.3.1 is met.

	Aeronautical telecommunication Volume - I		BCAR-10	
	Technical provision for GNSS		Appendix-B	Page: 189

3.5.14.3.6 Timing data

3.5.14.3.6.1 SBAS shall indicate on which reference time the SNT for DFMC SBAS is aligned through the time reference identifier field of the Type 37 message.

3.5.14.3.6.2 If an SBAS provides the $WNRO_{count}$ information with a parameter not permanently set to “15”, the SBAS shall monitor the week number rollover by updating the week number rollover count ($WNRO_{count}$) in the Type 47 message for the GNSS constellation identified by the time reference identifier in the Type 37 message.

Note.— The week number rollover count is used to solve the possible ambiguity of the week number value transmitted through the GNSS navigation data. Information on the reference time per constellation to compute the $WNRO_{count}$ can be found in 3.5.11.7.

3.5.14.3.6.3 If a Type 42 message is broadcast, SBAS shall provide information to derive the SNT-to-UTC offset in line with the information set in the VP parameter.

Note.— The UTC offset status parameter can be used by the SBAS to time-out previously broadcast information.

3.5.14.3.6.4 If a Type 42 message is broadcast and if a SNT-to-UTC offset cannot be broadcast by SBAS, SBAS shall broadcast all parameters in common parameter field with all bits coded to zero except the UTC standard identifier set to “7”.

3.5.14.4 Monitoring

3.5.14.4.1 *SBAS radio frequency monitoring.* The SBAS shall monitor the SBAS satellite parameters shown in Table B-109 and take the indicated action.

Note.— In addition to the radio frequency monitoring requirements in this section, it will be necessary to make special provisions to monitor the pseudo-range acceleration specified in Chapter 3, 3.7.3.4.3.5, carrier phase noise specified in 3.5.9.2, and correlation loss in 3.5.9.5, unless analysis and testing shows that these parameters cannot exceed the stated limits.

3.5.14.4.2 *Data monitoring.* The SBAS shall monitor GNSS ranging signals to ensure that active data meets the requirements of 3.5.14.3.1.

3.5.14.4.2.1 The ground subsystem shall lock on main correlation peaks of the tracked signals used for the SBAS augmentation.

3.5.14.4.2.2 The ground subsystem shall ensure that broadcast data bound the residual error for airborne receivers according to DFMC SBAS receiver design constraints defined in 3.5.15.1.1.3 when exposed to GNSS signal distortions defined in Attachment D, 8.

Note.— SBAS receiver locks on the main correlation peak of the tracked signal following the requirement in 3.5.15.1.5.

3.5.14.4.2.3 The monitor action shall be to set DFRE to a larger value or to “Do Not Use for SBAS” for the satellite.

3.5.14.4.2.4 SBAS shall monitor all active data that can be used by any user within the coverage area.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 190

3.5.14.4.2.5 SBAS shall raise an alert within 5.2 seconds if any combination of active data and GNSS signals-in-space results in a horizontal or vertical position error exceeding respectively the HPL or VPL (as per 3.5.14.3.1).

Note.— The monitoring applies to all failure conditions, including failures in core satellite constellation(s) or SBAS satellites. This monitoring assumes that the aircraft element complies with the requirements of 3.5.15.

3.5.14.4.3 *IOD monitoring.* SBAS shall take appropriate action to ensure integrity of the broadcast information when the active IODN as described in 3.5.11.2 can be linked to more than one valid ephemeris.

Note 1.— Active data is defined as data that has not timed out as per Table B-107. This requirement includes core satellite constellation(s) and SBAS failures.

Note 2.— Additional information on the application of SBAS corrections by an SBAS receiver is provided in 3.5.15.1.4.8 and can be used to assess the time during which a mismatch of IODN and core constellation can be considered by SBAS.

3.5.14.5 *Robustness to core constellation(s) failures.* SBAS shall continue to provide SBAS services after removal of one or several satellites, including a complete core constellation.

Note. — SBAS systems are expected to maintain operation in the presence of failures or anomalies on one or several satellites or failure of a complete core constellation. The level of supported service degrades as more satellites are removed. Removal of a failed or unhealthy satellite does not impact the ability to monitor and correct other satellites.

3.5.15 DFMC SBAS Aircraft Elements

Note 1.— The parameters that are referred to in this section are defined in 3.5.11.

Note 2.— Whereas all SBAS receivers process signals from SBAS GEO satellites, processing non-GEO SBAS signals is optional.

3.5.15.1 DFMC SBAS-capable GNSS receiver.

3.5.15.1.1 *DFMC SBAS-capable GNSS receiver.* Except as specifically noted, the DFMC SBAS-capable GNSS receiver shall process the signals of the SBAS and meet the requirements applicable to the core constellations it tracks as specified in 3.1.1.3.1 (GPS receiver), and/or 3.1.2.3.1 (GLONASS receiver), and/or 3.1.3.3.1 (Galileo receivers), and/or 3.1.4.3.1 (BDS receivers). Pseudo-range measurements for each satellite shall be smoothed using carrier measurements and the filter identified in 3.5.1.1 with the following pseudo-range observables:

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 191

- $P_{1,k}$ is the L1 C/A or L1OCd or E1-C or B1C_pilot or SBAS L1 raw pseudo-range measurement in metres;
- $P_{2,k}$ is the L5-Q or L3OCd or E5a-Q or B2a_pilot or SBAS L5 raw pseudo-range measurement in metres;
- $\varphi_{1,k}$ is the accumulated L1 C/A or L1OCd or E1-C or B1C_pilot or SBAS L1 raw carrier phase measurement in metres;
- $\varphi_{2,k}$ is the accumulated L5-Q or L3OCd or E5a-Q or B2a_pilot or SBAS L5 raw carrier phase measurement in metres;
- $\gamma_{12} = \left(\frac{f_1}{f_2}\right)^2$ is the square frequency ratio, where f_1 is L1 C/A or L1OCd or E1-C or B1C_pilot or SBAS L1 and f_2 is L5-Q or L3OCd or E5a-Q or B2a_pilot or SBAS L5; and
- α is the filter weighting function defined as follows: after 100 seconds have elapsed since filter initialization, α shall be equal to the sample interval in seconds divided by the time constant of 100 seconds. In the first 100 seconds since filter initialization, α shall be equal to the sample interval in seconds divided by the time in seconds since filter initialization.

3.5.15.1.1.1 The receiver shall process the augmented signals as follows:

- a) for GPS: the receiver shall use a BPSK(1) replica for L1 C/A signal and a BPSK(10) replica for L5-Q signal. The satellite position and satellite clock shall be based on ephemeris in LNAV message on L1. Group delay correction from LNAV message on L1 shall be applied;
- b) for GLONASS: the receiver shall use a BPSK(1) replica for L1OCd and a BPSK(10) replica for L3OCd signal. The satellite position and satellite clock shall be based on ephemeris in strings 10, 11 and 12 of L1OCd or L3OCd;
- c) for Galileo: the receiver shall use a BOC(1,1) replica for E1-C signal and a BPSK(10) replica for E5a-Q signal. The satellite position and satellite clock shall be based on ephemeris in F/NAV message on E5a; and
- d) for BDS: the receiver shall use a BOC(1,1) replica for B1C_pilot signal and a BPSK(10) replica for B2a_pilot signal. The satellite position and satellite clock shall be based on ephemeris in B-CNAV2 message on B2a.

Note.— The equivalent specific ionosphere-free computation is described in BDS-SIS-ICD-B2a (VI.0), 7.8.3 taking into account the group delays broadcast in B-CNAV2 message.

3.5.15.1.1.2 The satellite time correction ($\Delta t_{sv,i}$) for satellite i , defined in 3.5.12.4, shall be computed using the following information:

- a) for GPS: the satellite clock correction $\Delta t_{sv,i}$ shall be computed as described in 3.1.1.2.1.2 taking into account the group delay correction broadcast in the LNAV message;
- b) for GLONASS: the satellite clock correction $\Delta t_{sv,i}$ shall be computed as described in 3.1.2.2.2;
- c) for Galileo: the satellite clock correction $\Delta t_{sv,i}$ shall be computed as described in 3.1.3.2.2;
- d) for BDS: the satellite clock correction $\Delta t_{sv,i}$ shall be computed as described in 3.1.4.2.2.1; and
- e) for SBAS ranging satellite: the satellite clock correction $\Delta t_{sv,i}$ shall be computed as $\Delta t_{sv,i} = a_{gf0} + a_{gf1}\Delta t$ with a_{gf0} and a_{gf1} broadcast in the Type 39 message and Δt defined in 3.5.12.3.1.

3.5.15.1.1.3 *DFMC SBAS aircraft element design constraints.*

3.5.15.1.1.3.1 For processing of L1, L5, E1, E5a, B1C and B2a signals, the aircraft element shall comply with the following constraints:

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 192

- a) dB bandwidth between 12 and 24 MHz centred around 1 575.42 MHz and around 1 176.45 MHz;
- b) differential group delay not greater than 150 ns;
- c) early minus late discriminator;
- d) L1/E1/B1C correlator spacing between 0.08 and 0.12 L1 chips;
- e) L5/E5a/B2a correlator spacing between 0.9 chips and 1.1 L5 chips;
- f) frequency roll-off of at least 24 dB per octave until reaching a minimum attenuation to meet the performance objectives in the presence of interfering signals at the interference thresholds specified in 3.7;
- g) maintain the minimum attenuation to meet the performance objectives in the presence of interfering signals at the interference thresholds specified in 3.7; and
- h) filter centre frequencies around 1 575.42 MHz and 1 176.45 MHz within $\pm 10\%$ of the 3 dB bandwidth specified in a).

Note 1.— This requirement constrains the entire aircraft implementation of the DFMC SBAS capability and not only the DFMC SBAS receiver.

Note 2.— The 0 dB level corresponds to the filter’s normalized peak in-band response.

3.5.15.1.1.3.2 For processing of L1OC and L3OC signals, the aircraft element shall comply with the following constraints:

- a) 3 dB bandwidth between 12 and 24 MHz centred around 1 600.995 MHz and around 1 202.025 MHz;
- b) differential group delay not greater than 150 ns;
- c) early minus late discriminator;
- d) L1OC correlator spacing between 0.08 and 0.12 L1 chips;
- e) L3OC correlator spacing between 0.9 chips and 1.1 L5 chips;
- f) frequency roll-off of at least 24 dB per octave until reaching a minimum attenuation to meet the performance objectives in the presence of interfering signals at the interference thresholds specified in 3.7;
- g) maintain the minimum attenuation to meet the performance objectives in the presence of interfering signals at the interference thresholds specified in 3.7; and
- h) filter centre frequencies around 1 600.995 MHz and 1 202.025 MHz within $\pm 10\%$ of the 3 dB bandwidth specified in a).

Note 1.— This requirement constrains the entire aircraft implementation of the DFMC SBAS capability and not only the DFMC SBAS receiver.

Note 2.— The 0 dB level corresponds to the filter’s normalized peak in-band response.

3.5.15.1.2 *GEO SBAS satellite acquisition on L5.* The receiver shall be able to acquire and track GEO satellites for which a stationary receiver at the user receiver location would experience a Doppler shift as large as ± 337 Hz.

3.5.15.1.3 *Non-GEO SBAS satellite acquisition on L5.* The non-GEO SBAS capable receiver shall be able to acquire and track non-GEO satellites for which a stationary receiver at the user receiver location would experience a Doppler shift as large as ± 7 kHz.

Note.— Information on non-GEO Doppler range is available in Attachment D, 6.7.5.

3.5.15.1.4 Conditions of use of data on L5.

3.5.15.1.4.1 The receiver shall use data from an SBAS message only if the CRC of this message has been verified.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 193

3.5.15.1.4.2 The receiver shall use the information transmitted in DFMC messages only within the time-out period, defined in Table B-107, starting from the reception of the last bit of the message.

3.5.15.1.4.3 Upon reception of a Type 0 message, the receiver shall cease using all data received from this signal that have defined time-out intervals in Table B-107, except for the SBAS service provider identifier which can be used only for the SBAS acquisition process.

3.5.15.1.4.4 The receiver shall only apply integrity data for which Type 34, 35 or 36 messages IODM matches an active Type 31 message IODM.

3.5.15.1.4.5 The reception of new DFREI shall replace the old DFREI.

3.5.15.1.4.6 DFRECI requirements.

3.5.15.1.4.6.1 The receiver shall treat the reception of a DFRECI = 0 or a DFRECI = 2 as though it had received a new copy of the most recent, active DFREI previously received through Type 32, 34, 35, 36 or 40 messages.

3.5.15.1.4.6.2 Upon reception of a DFRECI = 2, the equipment shall use the most recent, active DFREI received through Types 32, 34, 35, 36 or 40 messages and use the σ_{DFRE} corresponding to the active DFREI increased by one.

Note.— The effect of the reception of a DFRECI = 2 (“value increase of 1”) is not cumulative.

3.5.15.1.4.6.3 Upon reception of a DFRECI = 3, the receiver shall set the DFREI to “15” (“Do Not Use for SBAS”) and exclude the satellite from the SBAS position solution.

3.5.15.1.4.6.4 Upon reception of a DFRECI = 1, the receiver shall update the DFREI value by decoding the corresponding DFREI slot in the order of a Type 34 message DFRECI set to “1” across the DFRECI field.

3.5.15.1.4.7 The receiver shall use the DFREI table through the latest decoded Type 37 message for the computation of σ_{DFRE} based on received DFREI.

3.5.15.1.4.8 Upon reception of the initial valid Type 32 message applicable to a given non-SBAS satellite, the receiver shall invalidate for this satellite any retained clock/ephemeris data set containing at least one parameter received for the last time more than 5 minutes before the reception of the initial valid Type 32 message.

Note.— The “initial valid Type 32 message” is the first Type 32 message received when there is no active Type 32 message from the SBAS L5 signal in use.

3.5.15.1.4.9 The receiver shall apply the ephemeris and clock parameters, the covariance matrix parameters, the OBAD parameters and the integrity parameters as described in 3.5.12.4 and 3.5.12.5.

3.5.15.1.4.10 The receiver shall use the content of Types 39 and 40 messages, only when Types 39 and 40 messages with the same IODG have been received and have not timed out.

3.5.15.1.4.11 The receiver shall correctly account for the day and week rollover change when observed after the last received Type 47 message.

3.5.15.1.4.12 The receiver shall only use SBAS augmented satellite ranges from satellites with elevation angles at or above 5 degrees in the DFMC SBAS position computation.

3.5.15.1.4.13 The receiver shall only use correction, integrity and other data obtained from a single SBAS satellite L5 signal, designated by its PRN code, for all satellites used in the position solution.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 194

Note.— When using additional SBAS satellites for ranging, the receiver uses the clock and ephemeris parameters in the Type 39/40 message from the ranging SBAS satellite(s), and the covariance and integrity parameters (e.g. DFREI, delta_RCORR) in the Type 32 message from the SBAS satellite being used for corrections.

3.5.15.1.4.14 Prior to use, the receiver shall verify that the tracked SBAS PRN code matches the PRN code derived from the satellite slot delta field within the almanac data upon reception of the Type 47 message with the broadcast indicator set to “1” or derived from the satellite slot delta field in an active Type 39 message.

3.5.15.1.4.15 In the event of a loss of four successive SBAS messages, the receiver shall invalidate all DFREIs and DFRECI previously received from this SBAS PRN.

3.5.15.1.4.16 The receiver shall check that the tD parameter in Type 32 message, as well as te and aGf0 parameters in Type 39/40 message, are within the effective range indicated in the message tables under 3.5.13. If the effective range check fails, the message shall be discarded.

Note.— Message bits or fields marked as “Reserved” or “Spare” may take any value during the operational lifetime of the SBAS service.

3.5.15.1.5 The SBAS receiver shall lock on main correlation peak of each of the tracked signals augmented by the SBAS and used in the SBAS position solution.

3.5.15.2 SBAS satellite position

3.5.15.2.1 Position computation with ephemeris. When using SBAS ranging, the receiver shall decode Type 39/40 messages and determine the position (XG, YG, ZG) of the SBAS satellite using the protocol described in 3.5.12.3.

3.5.15.2.2 Position computation with almanac. When computing the SBAS satellite position using a Type 47 message, the receiver shall determine the position (XG, YG, ZG) of the SBAS satellite using the protocol described in 3.5.12.2.

3.5.15.3 Ionosphere-free differential functions

3.5.15.3.1 GNSS satellite status function. The receiver shall exclude satellites from the SBAS position solution if they are identified as “Do Not Use for SBAS”.

Note 1.— In the case of a satellite designated marginal or unhealthy by the core satellite constellation(s) health flags, SBAS may broadcast ephemeris and clock corrections that will allow the user to continue using the satellite as long as performance requirements in 3.5.14.3.1 are met.

Note 2.— If satellites identified as “Do Not Use for SBAS” by SBAS are used in the position solution, integrity is not provided by SBAS.

3.5.15.3.2 Core satellite constellation(s) ranging accuracy for precision approach. The RMS (1 sigma) of the total airborne contribution in steady state to the error in a corrected ionosphere-free pseudo-range shall be less than or equal to the value in Table B-114 at minimum and maximum power levels.

Table B-122. Core constellation satellite ionosphere-free receiver ranging accuracy for precision approach

	<i>GPS</i> (See Chapter 3, 3.7.3.1.1.8.6)	<i>GLONASS</i> (See Chapter 3, 3.7.3.1.2.9.4 and 3.7.3.1.2.10.4)	<i>Galileo</i> (See Chapter 3, 3.7.3.1.3.11.1 and 3.7.3.1.3.11.2)	<i>BDS</i> (See Chapter 3, 3.7.3.1.4.9.4.1 and 3.7.3.1.4.10.4.1)
Minimum power level	0.4 m	0.65 m	0.4 m	0.4 m
Maximum power level	0.3 m	0.3 m	0.3 m	0.3 m

3.5.15.3.3 The receiver shall use the protocol described in 3.5.12.4 for the SBAS position solution and for the constellation time difference if more than one constellation is augmented by the SBAS.

3.5.15.3.4 The receiver shall compute the SBAS horizontal and vertical protection levels as defined in 3.5.12.5.

3.5.15.3.4.1 The airborne receiver error variance $\sigma_{air,DF}^2$ for satellite i shall be computed as follows:

$$\sigma_{air,DF}^2[i] = \sigma_{noise}^2[i] + \sigma_{MP\&AGDV,DF}^2[i]$$

where

$\sigma_{noise}^2[i]$ is defined in 3.5.15.3.2;

$\sigma_{MP\&AGDV,DF}^2$, the multipath and antenna group delay variation error model for ionosphere-free dual-

frequency 100-second smoothed measurements, described by a normal distribution with zero mean and a standard deviation of:

for GPS, Galileo, GLONASS and BDS: $\sigma_{MP\&AGDV,DF}[i] = 0.34 + 0.4 \exp(-El_{deg}[i]/14^\circ)$ (in metres);
and

where $El_{deg}[i]$ is the elevation angle of satellite i (in degrees).

3.5.15.3.4.2 For ionosphere-free dual-frequency measurements, the residual ionospheric uncertainty shall be defined as:

$$\sigma_{i,iono} = \frac{40.0}{261.0 + (El_{deg}[i])^2} + 0.018 \text{ (in metres)}$$

where $El_{deg}[i]$ is the elevation angle (in degrees) of satellite i .

3.5.15.3.5 The parameters in the SBAS FAS data block applicable to DFMC SBAS receivers shall be as described in 3.5.8.4.2.6 with the exception of the operation type and the approach performance designator as described below:

	Aeronautical telecommunication Volume - I		BCAR-10	
	Technical provision for GNSS		Appendix-B	Page: 196

Operation type: straight-in approach procedure or other operation types applicable to DFMC SBAS receivers.

- Coding: 0 = straight-in approach procedure with SPID from 0 to 13
1 to 7 = spare
8 = straight-in approach procedure with SPID from 16 to 31
9 to 15 = spare

Approach performance designator (APD): shall indicate the SBAS service supporting the requirements in accordance with Table 3.7.2.4-1 for the approach defined by the FAS data block, including the completion of a system-specific safety analysis for Category 1 if the vertical alert limit (VAL) in the FAS data block is greater than 10 m.

- Coding: 0 = DFMC SBAS or L1 SBAS service
1 = DFMC SBAS service augmenting one or more constellations (L1 SBAS not supported)
2 = DFMC SBAS service augmenting at least two constellations (L1 SBAS not supported)
3 to 4 = Spare
5 = DFMC SBAS service augmenting one or more constellations (L1 SBAS with reduced continuity/availability)
6 = DFMC SBAS service augmenting at least two constellations (L1 SBAS with reduced continuity/availability)
7 = Spare

Note 1.— The different APD coding values are intended to communicate potential performance differences available from the SBAS services at the approach location based on the number of GNSS frequencies and the number of augmented constellations used. Only DFMC SBAS airborne receivers use the APD to select the appropriate airborne receiver mode to support the operation. Further information can be found in Attachment D, 6.6.5.

Note 2.— “L1 SBAS not supported” means that, for a Category I approach, the L1 SBAS service in the approach region does not meet the system-specific safety assessment for the published VAL. See also the guidance in Attachment D, 3.3.9 and 6.6.5.

Note 3.— “L1 SBAS service with reduced continuity/availability” means that the L1 SBAS service in the approach region does not meet the availability or continuity requirements for the approach. Additional aircraft element integration may be used to satisfy availability and continuity requirements for the approach. The determination of the SBAS-based position domain NSE availability and continuity, using additional aircraft element system integration, and the assessment of the suitability of that availability and continuity for the approach, is the responsibility of the aircraft element. For a Category 1 approach, the L1 SBAS service does meet the system-specific safety assessment for the published VAL, following the guidance in Attachment D, 3.3.9 and 6.6.5.

3.5.15.3.5.1 For operations defined by a FAS data block, the receiver shall determine the operational SBAS service provider identifier (SPID) applicable to the operation as follows: if the operation type is 0, the operational SPID shall be the value of the FAS data block SPID; if the operation type is 8, the operational SPID shall be the sum of 16 and the value of the FAS data block SPID.

3.5.15.3.5.2 For operations defined by a FAS data block and the operational SPID is not 15, the receiver shall select SBAS signals with an active SPID decoded from a received Type 47 message that matches the operational SPID determined from the FAS data block (see 3.5.15.3.5.1).

3.5.15.3.5.3 For operations defined by a FAS data block, the receiver shall use the APD to determine the acceptable combination of SBAS navigation service (i.e. DFMC SBAS and/or L1 SBAS) and the number of constellations required to support the intended operation (see Attachment D, 6.6.5).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 197

3.5.15.3.5.4 For operations defined by a FAS data block with an operational SPID of 15 and an APD of two or six, the receiver shall select SBAS satellites that augment two or more constellations that can be used by the receiver.

Note. — If the operational SPID is 15 and the APD is not two or six, the receiver can select any operational SBAS (not broadcasting MTO).

3.5.15.4 Ranging function

3.5.15.4.1 *DFMC SBAS satellite ranging accuracy.* The root-mean-square (1 sigma) of the total airborne contribution in steady state to the error in a corrected ionosphere-free pseudo-range for a dual-frequency SBAS ranging satellite under the worst interference environment as defined in 3.7, excluding multipath effects, tropospheric and ionospheric residual errors, shall be less than or equal to 0.8 metres at the minimum received signal power level or equal to 0.6 metres at the maximum received signal power level (Chapter 3, 3.7.3.4.6.3).

3.5.15.5 Timing function

3.5.15.5.1 If a UTC time is derived from an SBAS receiver through a Type 42 message, the receiver shall time-out previously received SNT-to-UTC information if the receiver decodes a UTC offset status set to 1.

3.5.15.5.2 If a UTC time is derived from an SBAS receiver through a Type 42 message, the receiver shall not apply the content of the received Type 42 message if the UTC standard identifier is set to 7.

Note. — The receiver may still use previously received information if not timed-out and if the UTC offset status is set to 0 in the received Type 42 message.

3.5.16 Interface Between SBAS

Note - Guidance material on the interface between different SBAS service providers is given in Attachment D, 6.3.

3.6 Ground-based augmentation system (GBAS) and ground-based regional augmentation system (GRAS)

3.6.1 General

The GBAS shall consist of a ground subsystem and an aircraft subsystem. The GBAS ground subsystem shall provide data and corrections for the GNSS ranging signals over a digital VHF data broadcast to the aircraft subsystem. The GRAS ground subsystem shall consist of one or more GBAS ground subsystems.

Note 1 - Guidance material is provided in Attachment D, 7.1.

Note 2.— GBAS SARPs have not yet been updated to support dual-frequency multi-constellation (DFMC) use. These SARPs are applicable to GPS L1 C/A and GLONASS L1OF only. Throughout the GBAS SARPs (Appendix B, 3.6) and in the GBAS sections of Attachment D, the term GLONASS should be understood to refer to GLONASS L1OF signals and services only, and the term GPS should be understood to refer to GPS L1 C/A signals and services only.

3.6.1.1 *GBAS service types.* A GBAS ground subsystem shall support either the positioning service, approach service or both types of service.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 198

Note 1.— Service types refers to a matched set of ground and airborne functional and performance requirements that ensure that quantifiable navigation performance is achieved by the airborne equipment. Guidance material concerning service types is given in Attachment D, 7.1.

Note 2.— GBAS ground facilities are characterized by a GBAS facility classification (GFC). Many GBAS performance and functional requirements depend on the GFC. These SARPs are organized according to which requirements apply for a given facility classification element (i.e. the facility approach service type (FAST) letter, the facility polarization etc.). Guidance material concerning facility classifications is given in Attachment D, 7.1.4.1).

3.6.1.2 All GBAS ground subsystems shall comply with the requirements of 3.6.1, 3.6.2, 3.6.3, 3.6.4, 3.6.6. and 3.6.7 unless otherwise stated. A FAST D ground subsystem shall also comply with all FAST C requirements in addition to the specific FAST D requirements.

3.6.2 RF Characteristics

3.6.2.1 Carrier frequency stability. The carrier frequency of the data broadcast shall be maintained within ± 0.0002 per cent of the assigned frequency.

3.6.2.2 Bit-to-phase-change encoding. GBAS messages shall be assembled into symbols, each consisting of 3 consecutive message bits. The end of the message shall be padded by 1 or 2 fill bits if necessary to form the last 3-bit symbol of the message. Symbols shall be converted to D8PSK carrier phase shifts (φ_k) in accordance with Table B-58.

Note.— The carrier phase for the k^{th} symbol (φ_k) is given by: $\varphi_k = \varphi_{k-1} + \varphi_k$. The D8PSK signal may be produced as shown in Figure B-19 by combining two quadrature RF signals which are independently suppressed-carrier amplitude-modulated by base band filtered impulses. A positive increase in φ_k represents a counterclockwise rotation in the complex I-Q plane of Figure B-19.

3.6.2.3 Modulation wave form and pulse shaping filters. The output of differential phase encoder shall be filtered by a pulse shaping filter whose output, $s(t)$, is described as follows:

$$S(t) = \sum_{k=-\infty}^{k=\infty} e^{j\phi_k} h(t - kT)$$

where

h = the impulse response of the raised cosine filter

ϕ_k = (as defined in 3.6.2.2);

t = time; and

T = the duration of each symbol = 1/10 500 second.

This pulse shaping filter shall have a nominal complex frequency response of a raised - cosine filter with $f_i = 0.6$. The time response, h(t), and frequency response, H(f), of the base band filters shall be as follows :

$$h(t) = \frac{\sin\left(\frac{\pi t}{T}\right) \cos\left(\frac{\pi t}{T}\right)}{\frac{\pi}{T} \left[1 - \left(\frac{2\alpha t}{T}\right)^2 \right]}$$

$$H(f) = \begin{cases} 1 & \text{for } 0 \leq f \leq \frac{1-\alpha}{2T} \\ \frac{1 - \sin\left(\frac{\pi}{2\alpha}(2fT - 1)\right)}{2} & \text{for } \frac{1-\alpha}{2T} \leq f \leq \frac{1+\alpha}{2T} \\ 0 & \text{for } f \geq \frac{1+\alpha}{2T} \end{cases}$$

3.6.2.4 Error vector magnitude. The error vector magnitude of the transmitted signal shall be less than 6.5 per cent root-mean-square (1 sigma).

3.6.2.5 RF data rate. The symbol rate shall be 10 500 symbols per second ± 0.005 per cent, resulting in a nominal bit rate of 31 500 bits per second.

Table B-123. Data encoding

Message bits			Symbol phase shift
I_{3k-2}	I_{3k-1}	I_{3k}	$\Delta\phi_k$
0	0	0	$0\pi/4$
0	0	1	$1\pi/4$
0	1	1	$2\pi/4$
0	1	0	$3\pi/4$
1	1	0	$4\pi/4$
1	1	1	$5\pi/4$
1	0	1	$6\pi/4$
1	0	0	$7\pi/4$

Note.— I_j is the j^{th} bit of the burst to be transmitted, where I_1 is the first bit of the training sequence.

3.6.2.6 Emissions in unassigned time slots. Under all operating conditions, the maximum power over a 25 kHz channel bandwidth, centered on the assigned frequency, when measured over any unassigned time slot, shall not exceed -105 dBc referenced to the authorized transmitter power.

Note - The -105 dBc may not protect reception of emissions in a slot assigned to another desired transmitter for receivers within 80 meters from the undesired transmitting antenna.

3.6.3 Data Structure

3.6.3.1 Transmitter Timing

3.6.3.1.1 Data broadcast timing structure. The time division multiple access (TDMA) timing structure shall be based on frames and time slots. Each frame shall be 500 milliseconds in duration. There shall be 2 such frames contained in each 1-second UTC epoch. The first of these frames shall start at the beginning of the UTC epoch and the second frame shall start 0.5 seconds after the beginning of the UTC epoch. The frame shall be time division multiplexed such that it shall consist of 8 individual time slots (A to H) of 62.5-millisecond duration.

3.6.3.1.2 Bursts. Each assigned time slot shall contain at most 1 burst. To initiate the use of a time slot, the GBAS shall broadcast a burst in that time slot in each of 5 consecutive frames. For each time slot in use, the ground subsystem shall broadcast a burst in at least 1 frame of every 5 consecutive frames.

Note 1 - Bursts contain one or more messages and may be of variable length up to the maximum allowed within the slot as required by 3.6.3.2.

Note 2 - During time slot initiation, the airborne receiver may not receive the first 4 bursts.

3.6.3.1.3 Timing budget for bursts

3.6.3.1.3.1 Each burst shall be contained in a 62.5-millisecond time slot.

3.6.3.1.3.2 The beginning of the burst shall occur 95.2 microseconds after the beginning of the time slot with a tolerance of ± 95.2 microseconds.

3.6.3.1.3.3 For GBAS/E equipment, the start of the synchronization and ambiguity resolution portion of the burst, transmitted with horizontal polarization (HPOL), shall occur within 10 microseconds of the start of the burst transmitted with vertical polarization (VPOL).

Note - Table B-59 illustrates the burst timing.

3.6.3.1.4 Ramp-up and transmitter power stabilization. The transmitter shall ramp up to 90 per cent of the steady-state power level within 190.5 microseconds after the beginning of the burst (2 symbols). The transmitter shall stabilize at the steady-state power within 476.2 microseconds after the beginning of the burst (5 symbols).

Note - The transmitter power stabilization period may be used by the aircraft receiver to settle its automatic gain control.

3.6.3.1.5 Ramp-down. After the final information symbol is transmitted in an assigned time slot, the transmitter output power level shall decrease to at least 30 dB below the steady-state power within 285.7 microseconds (3 symbols).

3.6.3.2 Burst organization and coding. Each burst shall consist of the data elements shown in Table B-60. Encoding of the messages shall follow the sequence: application data formatting, training sequence forward error correction (FEC) generation, application FEC generation and bit scrambling.

3.6.3.2.1 Synchronization and ambiguity resolution. The synchronization and ambiguity resolution field shall consist of the 48-bit sequence shown below, with the rightmost bit transmitted first:

010 001 111 101 111 110 001 100 011 101 100 000 011 110 010 000

Table B-124. Burst timing

<i>Event</i>	<i>Nominal event duration</i>	<i>Nominal percentage of steady-state power</i>
Ramp-up	190.5 μs	0% to 90%
Transmitter power stabilization	285.7 μs	90% to 100%
Synchronization and ambiguity resolution	1 523.8 μs	100%
Transmission of scrambled data	58 761.9 μs	100%
Ramp-down	285.7 μs (<i>Note 1</i>)	100% to 0%

Notes.—

- Event duration indicated for transmission of scrambled data is for maximum application data length of 1 776 bits, 2 fill bits and nominal symbol duration.*
- These timing requirements provide a propagation guard time of 1 259 microseconds, allowing for a one-way propagation range of approximately 370 km (200 NM).*
- Where bursts from a GBAS broadcast antenna can be received at a range more than 370 km (200 NM) greater than the range from another broadcast antenna using the next adjacent slot, a longer guard time is required to avoid loss of both bursts. To provide a longer guard time, it is necessary to limit the application data length of the first burst to 1 744 bits. This allows a difference in propagation ranges of up to 692 km (372 NM) without conflict.*

Table B-125. Burst data content

<i>Element</i>	<i>Data content</i>	<i>Number of bits</i>
Beginning of burst	all zeros	15
Power stabilization		
Synchronization and ambiguity resolution	3.6.3.2.1	48
Scrambled data:	3.6.3.3	
station slot identifier (SSID)	3.6.3.3.1	3
transmission length	3.6.3.3.2	17
training sequence FEC	3.6.3.3.3	5
application data	3.6.3.3.4	up to 1 776
application FEC	3.6.3.3.5	48
fill bits (Note)	3.6.2.2	0 to 2

Note.— Data scrambling of the fill bits is optional (3.6.3.3.6).

3.6.3.3 Scrambled Data Content

3.6.3.3.1 Station slot identifier (SSID). The SSID shall be a numeric value corresponding to the letter designation A to H of the first time slot assigned to the GBAS ground subsystem, where slot A is represented by 0, B by 1, C by 2, ... and H by 7. The identifier is transmitted LSB first.

3.6.3.3.2 Transmission length. The transmission length shall indicate the total number of bits in both application data and application FEC. The transmission length is transmitted LSB first.

3.6.3.3.3 Training sequence FEC. The training sequence FEC shall be computed over the SSID and transmission length fields, using a (25, 20) block code, in accordance with the following equation:

$$[P_1, \dots, P_5] = [\text{SSID}_1, \dots, \text{SSID}_3, \text{TL}_1, \dots, \text{TL}_{17}] H^T$$

where

- P_n = the n^{th} bit of the training sequence FEC (P_1 shall be transmitted first);
- SSID_n = the n^{th} bit of the station slot identifier ($\text{SSID}_1 = \text{LSB}$);
- TL_n = the n^{th} bit in the transmission length ($\text{TL}_1 = \text{LSB}$); and
- H^T = the transpose of the parity matrix, defined below:

$$H^T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \end{bmatrix}^T$$

Note - This code is capable of correcting all single bit errors and detecting 75 of 300 possible double bit errors.

3.6.3.3.4 Application data. The application data shall consist of one or more message blocks, as defined in 3.6.3.4. The message blocks shall be mapped directly into the application data with no additional overhead of intervening layers.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 203

3.6.3.3.5 Application FEC. The application FEC shall be calculated using the application data by means of a systematic, fixed-length, Reed-Solomon (R-S) (255, 249) code.

3.6.3.3.5.1 The field-defining primitive, $p(x)$, of the R-S code shall be:

$$p(x) = x^8 + x^7 + x^2 + x + 1$$

3.6.3.3.5.2 The generator polynomial of the R-S code, $g(x)$, shall be:

$$g(x) = \prod_{i=120}^{125} (x - \alpha^i) = x^6 + \alpha^{176}x^5 + \alpha^{186}x^4 + \alpha^{244}x^3 + \alpha^{176}x^2 + \alpha^{156}x + \alpha^{225}$$

where α is a root of $p(x)$ used for construction of the Galois Field of size 2^8 , GF(256), and α^i is the i^{th} primitive element in GF(256).

3.6.3.3.5.3 In generating the application FEC, the data to be encoded, $m(x)$, shall be grouped into 8-bit R-S symbols. All data fields in the message blocks that define the application data shall be ordered such as specified in Tables B-61 and B-62, and in the message tables in 3.6.6. However, since the R-S code is a block code, application data blocks shorter than 249 bytes (1 992 bits) shall be extended to 249 bytes by virtual fill bits set to zero and appended to the application data. These virtual fill bits shall not be transferred to the bit scrambler. The data to be encoded, $m(x)$, shall be defined by:

$$m(x) = a_{248}x^{248} + a_{247}x^{247} + \dots + a_{248-\text{length}+1}x^{248-\text{length}+1} + a_{248-\text{length}}x^{248-\text{length}} + \dots + a_1x + a_0$$

where

length represents the number of 8-bit bytes in the application data block;

a_{248} represents the message block identifier, with the rightmost bit defined as the LSB and the first bit of the application data sent to the bit scrambler;

$a_{248-\text{length}+1}$ represents the last byte of the message block CRC, with the leftmost bit defined as the MSB and the last bit of the application data sent to the bit scrambler; and

$a_{248-\text{length}}, \dots, a_1, a_0$ are the virtual fill bits (if any).

3.6.3.3.5.4 The 6 R-S check symbols (b_i) shall be defined as the coefficients of the remainder resulting from dividing the message polynomial $x^6m(x)$ by the generator polynomial $g(x)$:

$$b(x) = \sum_{i=0}^5 b_i x^i + b_5 x^5 + b_4 x^4 + b_3 x^3 + b_2 x^2 + b_1 x^1 + b_0 = [x^6 m(x)] \bmod g(x)$$

3.6.3.3.5.5 The 8-bit R-S check symbols shall be appended to the application data. Each 8-bit R-S check symbol shall be transmitted MSB first from b_0 to b_5 , i.e. the first application FEC bit transferred to the bit scrambler shall be the MSB of b_0 and the last application FEC bit transferred to the bit scrambler shall be the LSB of b_5 .

Note 1 - This R-S code is capable of correcting up to 3 symbol errors.

Note 2 - The order of the transmitted 8-bit R-S check symbols of the appended application FEC differs from the VHF data link (VDL) Mode 2. Moreover, for VDL Mode 2 each R-S check symbol is transmitted LSB first.

Note 3 - Example results of application FEC encoding are given in Attachment D, 7.15

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024

Message	up to 1 696
CRC	32

Table B-127. Format of message block header

<i>Data field</i>	<i>Bits</i>
Message block identifier	8
GBAS ID	24
Message type identifier	8
Message length	8

3.6.3.3.6 Bit scrambling

3.6.3.3.6.1 The output of a pseudo-noise scrambler with a 15-stage generator register shall be exclusive OR'ed with the burst data starting with the SSID and ending with the application FEC. Bit scrambling of the fill bits is optional and the set value of the fill bits is optional.

Note - The fill bits are not used by the aircraft receiver and their values have no impact on the system.

3.6.3.3.6.2 The polynomial for the register taps of the scrambler shall be $1 + x + x^{15}$. The register content shall be rotated at the rate of one shift per bit. The initial status of the register, prior to the first SSID bit of each burst, shall be “1101 0010 1011 001”, with the leftmost bit in the first stage of the register. The first output bit of the scrambler shall be sampled prior to the first register shift.

Note - A diagram of the bit scrambler is given in Attachment D, 7.4.

3.6.3.4 Message block format. The message blocks shall consist of a message block header, a message and a 32-bit CRC. Table B-61 shows the construction of the message block. All signed parameters shall be two's complement numbers and all unsigned parameters shall be unsigned fixed point numbers. The scaling of the data shall be as shown in the message tables in 3.6.6. All data fields in the message block shall be transmitted in the order specified in the message tables, with the LSB of each field transmitted first.

Note - All binary representations reading left to right are MSB to LSB.

3.6.3.4.1 Message block header. The message block header shall consist of a message block identifier, a GBAS identifier (ID), a message type identifier and a message length, as shown in Table B-62.

Message block identifier: the 8-bit identifier for the operating mode of the GBAS message block.

Coding:

1010 1010 = normal GBAS message

1111 1111 = test GBAS message

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 205

All other values are reserved.

GBAS ID: the four-character GBAS identification to differentiate between GBAS ground subsystems.

Coding: Each character is coded using bits b_1 through b_6 of its International Alphabet No. 5 (IA-5) representation. For each character, bit b_1 is transmitted first and six bits are transmitted for each character. Only upper case letters, numeric digits and IA-5 “space” are used. The rightmost character is transmitted first. For a three-character GBAS ID, the rightmost (first transmitted) character shall be IA-5 “space”.

Note.— The GBAS ID is normally identical to the location indicator at the nearest airport. Assignment of GBAS IDs will be coordinated as appropriate to avoid conflicts.

Message type identifier: the numeric label identifying the content of the message (Table B-63).

Message length: the length of the message in 8-bit bytes including the 6-byte message block header, the message and the 4-byte message CRC code.

3.6.3.4.2 Cyclic redundancy check (CRC). The GBAS message CRC shall be calculated in accordance with 3.9.

3.6.3.4.2.1 The length of the CRC code shall be $k = 32$ bits.

3.6.3.4.2.2 The CRC generator polynomial shall be:

$$G(x) = x^{32} + x^{31} + x^{24} + x^{22} + x^{16} + x^{14} + x^8 + x^7 + x^5 + x^3 + x + 1$$

3.6.3.4.2.3 The CRC information field, $M(x)$, shall be:

$$M(x) = \sum_{i=1}^n m_i x^{n-i} + m_1 x^{n-1} + m_2 x^{n-2} + \dots + m_n x^0$$

3.6.3.4.2.4 $M(x)$ shall be formed from the 48-bit GBAS message block header and all bits of the variable-length message, excluding the CRC. Bits shall be arranged in the order transmitted, such that m_1 corresponds to the first transmitted bit of the message block header, and m_n corresponds to the last transmitted bit of the (n-48) message bits.

3.6.3.4.2.5 The CRC shall be ordered such that r_1 is the first bit transmitted and r_{32} is the last bit transmitted.

3.6.4 Data Content

3.6.4.1 Message types. The message types that can be transmitted by GBAS shall be as in Table B-63.

3.6.4.2 Type1 Message — Pseudo-Range Corrections

3.6.4.2.1 The Type 1 message shall provide the differential correction data for individual GNSS ranging sources (Table B-70). The message shall contain three sections:

- a) message information (time of validity, additional message flag, number of measurements and the measurement type);

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 206

- b) low-frequency information (ephemeris decorrelation parameter, satellite ephemeris CRC and satellite availability information); and
- c) satellite data measurement blocks.

Note1 - Transmission of the low-frequency data for SBAS ranging sources is optional.

Note 2.— All parameters in this message type apply to 100-second carrier-smoothed pseudo-ranges.

3.6.4.2.2 Each Type 1 message shall include ephemeris decorrelation parameter, ephemeris CRC and source availability duration parameters for one satellite ranging source. The ephemeris decorrelation parameter, ephemeris CRC and source availability duration shall apply to the first ranging source in the message.

3.6.4.2.3 Pseudo-range correction parameters shall be as follows:

Modified Z-count: the indication of the time of applicability for all the parameters in the message.

Coding: the modified Z-count resets on the hour (xx:00), 20 minutes past the hour (xx:20) and 40 minutes past the hour (xx:40) referenced to GPS time.

Additional message flag: an identification of whether the set of measurement blocks in a single frame for a particular measurement type is contained in a single Type 1 message or a linked pair of messages.

- Coding: 0 = All measurement blocks for a particular measurement type are contained in one Type 1 message.
1 = This is the first transmitted message of a linked pair of Type 1 messages that together contain the set of all measurement blocks for a particular measurement type.
2 = Spare
3 = This is the second transmitted message of a linked pair of Type 1 messages that together contain the set of all measurement blocks for a particular measurement type.

Note - When a linked pair of Type 1 messages is used for a particular measurement type, the number of measurements and low-frequency data are computed separately for each of the two individual messages.

Number of measurements: the number of measurement blocks in the message.

Measurement type: the type of ranging signal from which the corrections have been computed.

Table B-128. GBAS VHF data broadcast messages

<i>Message type identifier</i>	<i>Message name</i>
0	Spare
1	Pseudo-range corrections
2	GBAS-related data
3	Null message
4	Final approach segment (FAS) data
5	Predicted ranging source availability
6	Reserved
7	Reserved for national applications
8	Reserved for test applications
9 to 10	Spare
11	Pseudo-range corrections – 30-second smoothed pseudo-ranges
12 to 100	Spare
101	GRAS pseudo-range corrections
102 to 255	Spare

Note.— See 3.6.6 for message formats.

Coding: 0 = C/A or CSA code L1

- 1 = reserved
- 2 = reserved
- 3 = reserved
- 4 to 7 = spare

Ephemeris de correlation parameter (P): a parameter that characterizes the impact of residual ephemeris errors due to de correlation for the first measurement block in the message.

For a SBAS geostationary satellite, the ephemeris de correlation parameter, if transmitted, shall be coded as all zeros.

For GBAS ground subsystems that do not broadcast the additional data block 1 in the Type 2 message, the ephemeris de correlation parameter shall be coded as all zeros.

Ephemeris CRC: the CRC computed with the ephemeris data used to determine corrections for the first measurement block in the message. The ephemeris CRC for core satellite constellation(s) ranging sources shall be calculated in accordance with 3.9. The length of the CRC code shall be $k = 16$ bits. The CRC generator polynomial shall be:

$$G(x) = x^{16} + x^{12} + x^5 + 1$$

The CRC information field, $M(x)$, for a given satellite shall

$$M(x) = \sum_{i=1}^n m_i x^n + m_1 x^{n-1} + m_2 x^{n-2} + \dots + m_n x^0$$

For a GPS satellite, $M(x)$ shall be of length $n = 576$ bits. $M(x)$ for a GPS satellite shall be calculated using the first 24 bits from each of words 3 to S10 of sub-frames 1, 2 and 3 of the data transmission from that satellite, ANDed with the GPS satellite ephemeris mask of Table B-64. $M(x)$ shall be arranged in the order that bytes are transmitted by the GPS satellite, but with each byte ordered LSB first, such that m_1 corresponds to bit 68 of sub-frame 1, and m_{576} corresponds to bit 287 of sub-frame 3.

Note.— $M(x)$ for a GPS satellite does not include word 1 (TLM) or word 2 (HOW), which start each sub-frame, or the 6 parity bits at the end of each word.

For a GLONASS satellite, $M(x)$ shall be of length $n = 340$ bits. $M(x)$ for a GLONASS satellite shall be calculated using strings 1, 2, 3 and 4 of the data transmission from that satellite, ANDed with the GLONASS satellite ephemeris mask of Table B-65. Bits shall be arranged in transmission order such that m_1 corresponds to bit 85 of string 1, and m_{340} corresponds to bit 1 of string 4.

For a SBAS geostationary satellite, the ephemeris CRC, if transmitted shall be coded as all zeros.

The CRC shall be transmitted in the order $r_9, r_{10}, r_{11}, \dots, r_{16}, r_1, r_2, r_3, \dots, r_8$, where r_i is the i^{th} coefficient of the remainder $R(x)$ as defined in 3.9.

Source availability duration: the predicted duration for which corrections for the ranging source are expected to remain available, relative to the modified Z-count for the first measurement block.

Coding: 1111 1110 = The duration is greater than or equal to 2 540 seconds.

1111 1111 = Prediction of source availability duration is not provided by this ground subsystem.

3.6.4.2.4 The measurement block parameters shall be as follows:

Ranging source ID: the identity of the ranging source to which subsequent measurement block data are applicable.

Table B-129. GPS satellite ephemeris mask

Subframe 1:	Byte 1	Byte 2	Byte 3	Byte 1	Byte 2	Byte 3

Table B-130. GLONASS satellite ephemeris mask

<pre>String 1: 0 0000 0000 0000 0000 0000 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 0000 0000 String 2: 0 0000 0000 0000 0000 0000 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 0000 0000 String 3: 0 0000 0111 1111 1111 0000 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 0000 0000 String 4: 0 0000 1111 1111 1111 1111 1111 1100 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000</pre>

Coding: 1 to 36 = GPS satellite IDs (PRN)
 37 = reserved
 38 to 61 = GLONASS satellite IDs (slot number plus 37)
 62 to 119 = spare
 120 to 158 = SBAS satellite IDs (PRN)
 159 to 255 = spare

Issue of data (IOD): The issue of data associated with the ephemeris data used to determine pseudo-range and range rate corrections.

Coding: for GPS, IOD = GPS IODE parameter (3.1.1.3.2.2)

for GLONASS, IOD = GLONASS “t_b” parameter (see 3.2.1.3.1)

for SBAS, IOD = 1111 1111

Note - For GLONASS insert 0 in the MSB of the IOD.

Pseudo-range correction (PRC): the correction to the ranging source pseudo-range.

Range rate correction (RRC): the rate of change of the pseudo-range correction.

σ_{pr_gnd} : the standard deviation of a normal distribution associated with the signal-in-space contribution of the pseudo-range error at the GBAS reference point (3.6.5.5.1, 3.6.5.5.2 and 3.6.7.2.2.4).

Coding: 1111 1111 = Ranging source correction invalid.

B₁ through B₄: are the integrity parameters associated with the pseudo-range corrections provided in the same measurement block. For the ith ranging source these parameters correspond to B_{i,1} through B_{i,4} (3.6.5.5.1.2, 3.6.5.5.2.2 and 3.6.7.2.2.4). During continuous operation the indices “1-4” correspond to the same physical reference receiver for every epoch transmitted from a given ground subsystem with the following exception: the physical reference receiver tied to any of the indices 1 to 4 can be replaced by any other physical reference receiver (including a previously removed one) that has not been used for transmissions during the last 5 minutes.

Coding: 1000 0000 = Reference receiver was not used to compute the pseudo-range correction.

Note 1.— A physical reference receiver is a receiver with an antenna at a fixed location.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 210

Note 2- Some airborne inertial integrations may expect a largely static correspondence of the reference receivers. Refer to RTCA/DO-253D, Appendix L.

3.6.4.3 Type 2 message - GBAS-related data. Type 2 message shall identify the location of the GBAS reference point at which the corrections provided by the GBAS apply and shall give other GBAS-related data (Table B-71). GBAS-related data parameters shall be as follows:

Note - Additional data blocks may be included in the Type 2 message. Additional data block 1 and additional data block 2 are defined. In the future, other additional data blocks may be defined. Data blocks 2 through 255 are variable length and may be appended to the message after additional data block 1 in any order.

GBAS reference receivers: the number of GNSS reference receivers installed in this GBAS ground subsystem.

Coding: 0 = GBAS installed with 2 reference receivers

1= GBAS installed with 3 reference receivers

2= GBAS installed with 4 reference receivers

3= The number of GNSS reference receivers installed in this GBAS ground subsystem is not applicable

Ground accuracy designator letter: the letter designator indicating the minimum signal-in-space accuracy performance provided by GBAS (3.6.7.1.1).

Coding: 0 = accuracy designation A

1 = accuracy designation B

2 = accuracy designation C

3 = spare

GBAS continuity/integrity designator (GCID): numeric designator indicating the operational status of the GBAS.

Coding: 0 = spare

1 = GCID 1

2 = GCID 2

3 = GCID 3

4 = GCID 4

5 = spare

6 = spare

7 = unhealthy

Note 1 - The values of GCID, 3 and 4 are specified in order to ensure compatibility of equipment with future GBAS.

Note 2 - The value of GCID 7 indicates that all approach services supported by the ground facility are unavailable.

Local magnetic variation: the published magnetic variation at the GBAS reference point.

Coding: Positive value denotes east variation (clockwise from true north), Negative value denotes west variation (counter-clockwise from true north) 100 0000 0000 = Precision approach procedures supported by this GBAS are published based on true bearing.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 211

Note.— Local magnetic variation is chosen to be consistent with procedure design and is updated during magnetic epoch years.

$\sigma_{\text{vert_iono_gradient}}$: the standard deviation of a normal distribution associated with the residual ionospheric uncertainty due to spatial decorrelation (3.6.5.4).

Refraction index (N_r): the nominal tropospheric refractivity index used to calibrate the tropospheric correction associated with the GBAS ground subsystem (3.6.5.3).

Coding: This field is coded as two's complement number with an offset of +400. A value of zero in this field indicates a refractivity index of 400.

Scale height (h_0): a scale factor used to calibrate the tropospheric correction and residual tropospheric uncertainty associated with the GBAS ground subsystem (3.6.5.3).

Refractivity uncertainty (σ_n): the standard deviation of a normal distribution associated with the residual tropospheric uncertainty (3.6.5.3).

Latitude: the latitude of the GBAS reference point defined in arc seconds.

Coding: Positive value denotes north latitude.

Negative value denotes south latitude.

Longitude: the longitude of the GBAS reference point defined in arc seconds.

Coding: Positive value denotes east longitude.

Negative value denotes west longitude.

Reference point height: the height of the GBAS reference point above the WGS-84 ellipsoid.

3.6.4.3.1 Additional data block 1 parameters. Additional data block 1 parameters shall be as follows:

REFERENCE STATION DATA SELECTOR (RSDS): the numerical identifier that is used to select the GBAS ground subsystem.

Note - The RSDS is different from every other RSDS and every reference path data selector (RPDS) broadcast on the same frequency by every GBAS ground subsystem within the broadcast region.

Coding: 1111 1111 = GBAS positioning service is not provided

MAXIMUM USE DISTANCE (D_{max}): the maximum distance (slant range) from the GBAS reference point within which pseudo-range corrections are applied by the aircraft element.

Note.— This parameter does not indicate a distance within which VHF data broadcast field strength requirements are met.

Coding: 0 = No distance limitation

GPS EPHEMERIS MISSED DETECTION PARAMETER, GBAS Positioning Service ($K_{\text{md_e_POS,GPS}}$): the multiplier for computation of the ephemeris error position bound for the GBAS positioning service types A, B and C derived from the probability of missed detection given that there is an ephemeris error in a GPS satellite.

For GBAS ground subsystems that do not broadcast corrections for GPS ranging sources or that do not provide the GBAS positioning service, this parameter shall be coded as all zeros.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 212

GPS EPHEMERIS MISSED DETECTION PARAMETER, *GBAS approach service types A, B or C* ($K_{md_e_GPS}$): the multiplier for computation of the ephemeris error position bound for GBAS approach service types A, B and C derived from the probability of missed detection given that there is an ephemeris error in a GPS satellite.

For GBAS ground subsystems that do not broadcast corrections for GPS ranging sources, this parameter shall be coded as all zeros.

GLONASS EPHEMERIS MISSED DETECTION PARAMETER, GBAS Positioning Service ($K_{md_e_POS_GLONASS}$): the multiplier for computation of the ephemeris error position bound for the derived from the probability of missed detection given that there is an ephemeris error in a GLONASS satellite.

For GBAS ground subsystems that do not broadcast corrections for GLONASS ranging sources or that do not provide positioning service, this parameter shall be coded as all zeros.

GLONASS EPHEMERIS MISSED DETECTION PARAMETER, *GBAS approach service types A, B or C* ($K_{md_e_GLONASS}$): the multiplier for computation of the ephemeris error position bound for GBAS approach service types A, B and C derived from the probability of missed detection given that there is an ephemeris error in a GLONASS satellite.

For GBAS ground subsystems that do not broadcast corrections for GLONASS ranging sources, this parameter shall be coded as all zeros.

3.6.4.3.2 Additional data blocks. For additional data blocks other than additional data block 1, the parameters for each data block shall be as follows:

ADDITIONAL DATA BLOCK LENGTH: the number of bytes in the additional data block, including the additional data block length and additional data block number fields.

ADDITIONAL DATA BLOCK NUMBER: the numerical identifier of the type of additional data block.

Coding	0 to 1=	reserved
	2 =	additional data block 2, GRAS broadcast stations
	3 =	additional data block 3, GAST D parameters
	4 =	additional data block 4, VDB authentication parameters
	5 to 255=	spare

ADDITIONAL DATA PARAMETERS: the set of data defined in accordance with the additional data block number.

3.6.4.3.2.1 GRAS broadcast stations

Parameters for additional data block 2 shall include data for one or more broadcast stations as follows (Table B-65A):

CHANNEL NUMBER: the channel number, as defined in 3.6.5.7, associated with a GBAS broadcast station.

Note - The channel number in this field refers to a frequency and an RSDS.

Δ LATITUDE: the difference of latitude of a GBAS broadcast station, measured from the latitude provided in the latitude parameter of Type 2 message.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 213

Coding: Positive value denotes that the GBAS broadcast station is north of the GBAS reference point. Negative value denotes that the GBAS broadcast station is south of the GBAS reference point.

Δ LONGITUDE: the difference of longitude of a GBAS broadcast station, measured from the longitude provided in the longitude parameter of Type 2 message.

Coding: Positive value denotes that the GBAS broadcast station is east of the GBAS reference point. Negative value denotes that the GBAS broadcast station is west of the GBAS reference point.

Note - Guidance material concerning additional data block 2 is provided in Attachment D, 7.17.

3.6.4.3.2.2 GAST D parameters

Parameters for additional data block 3 shall include parameters (Table B-65B) to be used when the active service type is GAST D as follows:

$K_{md_e_D, GLONASS}$ ($K_{md_e_D, GLONASS}$): is the multiplier for computation of the ephemeris error position bound for GAST D derived from the probability of missed detection given that there is an ephemeris error in a GLONASS satellite. For GBAS ground sub-systems that do not broadcast corrections for GLONASS ranging sources, this parameter is coded as all zeros.

Note.— This parameter, $K_{md_e_D, GLONASS}$, may be different than the ephemeris decorrelation parameter $K_{md_e_D, GLONASS}$ provided in additional data block 1 of the Type 2 message. Additional information regarding the difference in these parameters is given in Attachment D, 7.5.6.1.2 and 7.5.6.1.3.

$K_{md_e_D, GPS}$ ($K_{md_e_D, GPS}$): is the multiplier for computation of the ephemeris error position bound for GAST D derived from the probability of missed detection given that there is an ephemeris error in a GPS satellite. For GBAS ground sub-systems that do not broadcast corrections for GPS ranging sources, this parameter is coded as all zeros.

Note.— This parameter, $K_{md_e_D, GPS}$, may be different than the ephemeris decorrelation parameter $K_{md_e_D, GPS}$ provided in additional data block 1 of the Type 2 message. Additional information regarding the difference in these parameters is given in Attachment D, 7.5.6.1.2 and 7.5.6.1.3.

$\sigma_{vert_iono_gradient_D}$ ($\sigma_{vert_iono_gradient_D}$): is the standard deviation of a normal distribution associated with the residual ionospheric uncertainty due to spatial decorrelation. This parameter is used by airborne equipment when its active approach service type is D.

Note.— This parameter, $\sigma_{vert_iono_gradient_D}$, may be different than the ionospheric decorrelation parameter $\sigma_{vert_iono_gradient}$ provided in the Type 2 message. Additional information regarding the difference in these parameters is given in Attachment D, 7.5.6.1.2 and 7.5.6.1.3.

E_{IG} : is the maximum value of E_{IG} at zero distance from the GBAS reference point. This parameter is used by airborne equipment when its active approach service type is D.

M_{EIG} : is the slope of maximum E_{IG} versus distance from the GBAS reference point. This parameter is used by airborne equipment when its active approach service type is D.

Table B-131. GRAS broadcast station data

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
Channel number	16	20001 to 39999	1
Δ Latitude	8	$\pm 25.4^\circ$	0.2°
Δ Longitude	8	$\pm 25.4^\circ$	0.2°

Table B-132. Additional data block 3 GAST D parameters

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
$K_{md_e_D, GPS}$	8	0 to 12.75	0.05
$K_{md_e_D, GLONASS}$	8	0 to 12.75	0.05
$\sigma_{vert_iono_gradient_D}$	8	0 to 25.5×10^{-6} m/m	0.1×10^{-6} m/m
Y_{EIG}	5	0 to 3.0 m	0.1
M_{EIG}	3	0 to 0.7 m/km	0.1

3.6.4.3.2.3 VDB authentication parameters

Additional data block 4 includes information needed to support VDB authentication protocols (Table B-65C).

Slot group definition: This 8-bit field indicates which of the 8 slots (A-H) are assigned for use by the ground station. The field is transmitted LSB first. The LSB corresponds to slot A, the next bit to slot B, and so on. A “1” in the bit position indicates the slot is assigned to the ground station. A “0” indicates the slot is not assigned to the ground station.

Table B-133. VDB authentication parameters

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
Slot group definition	8	—	—

3.6.4.4 Type 3 Message -NULL Message

3.6.4.4.1 The Type 3 message is a variable length “null message” which is intended to be used by ground subsystems that support the authentication protocols (see section 3.6.7.4).

3.6.4.4.2 The parameters for the Type 3 message shall be as follows:

Filler: a sequence of bits alternating between “1” and “0” with a length in bytes that is 10 less than the value in the message length field in the message header.

3.6.4.5 Type 4 message — Final approach segment (FAS). Type 4 message shall contain one or more sets of FAS data, each defining a single precision approach (Table B-72). Each Type 4 message data set shall include the following:

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 215

Data set length: the number of bytes in the data set. The data set includes the data set length field and the associated FAS data block, FAS vertical alert limit (FASVAL)/approach status and FAS lateral alert limit (FASLAL)/approach status fields.

FAS data block: the set of parameters to identify an approach and define its associated approach path.

Coding: See 3.6.4.5.1 and Table B-66.

Note - Guidance material for FAS path definition is contained in Attachment D, 7.11.

FASVAL/approach status: the value of the parameter FASVAL as used in 3.6.5.6.

Coding: 1111 1111 = Do not use vertical deviations.

Note - The range and resolution of values for FASVAL depend upon the approach performance designator in the associated FAS data block.

FASLAL/approach status: the value of the parameter FASLAL as used in 3.6.5.6.

Coding: 1111 1111 = Do not use approach.

Note.— The Procedures for Air Navigation Services — Aircraft Operations (PANS-OPS) (Doc 8168), Volume II, specifies conventions to be used by procedure designers when applying the FAS data block definitions and codings below to encode procedures.

3.6.4.5.1 FAS data block. The FAS data block shall contain the parameters that define a single GAST A, B, C or D-approach. The FAS path is a line in space defined by the landing threshold point/fictitious threshold point (LTP/FTP), flight path alignment point (FPAP), threshold crossing height (TCH) and glide path angle (GPA). The local level plane for the approach is a plane perpendicular to the local vertical passing through the LTP/FTP (i.e. tangent to the ellipsoid at the LTP/FTP). Local vertical for the approach is normal to the WGS-84 ellipsoid at the LTP/FTP. The glide path intercept point (GPIP) is where the final approach path intercepts the local level plane. FAS data block parameters shall be as follows:

Operation type: straight-in approach procedure or other operation types.

Coding: 0 = straight-in approach procedure

1 to 15 = spare

Note.— Offset procedures are straight-in procedures and coded as “0”.

Table B-134. Final approach segment (FAS) data block

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
Operation type	4	0 to 15	1
SBAS provider ID	4	0 to 15	1
Airport ID	32	—	—
Runway number	6	1 to 36	1
Runway letter	2	—	—
Approach performance designator	3	0 to 7	1
Route indicator	5	—	—
Reference path data selector	8	0 to 48	1
Reference path identifier	32	—	—
LTP/FTP latitude	32	±90.0°	0.0005 arcsec
LTP/FTP longitude	32	±180.0°	0.0005 arcsec
LTP/FTP height	16	-512.0 to 6 041.5 m	0.1 m
ΔFPAP latitude	24	±1.0°	0.0005 arcsec
ΔFPAP longitude	24	±1.0°	0.0005 arcsec
Approach TCH (Note)	15	0 to 1 638.35 m or 0 to 3 276.7 ft	0.05 m or 0.1 ft
Approach TCH units selector	1	—	—
GPA	16	0 to 90.0°	0.01°
Course width	8	80 to 143.75 m	0.25 m
ΔLength offset	8	0 to 2 032 m	8 m
Final approach segment CRC	32	—	—

Note.— Information can be provided in either feet or metres as indicated by the approach TCH unit selector.

SBAS service provider ID: indicates the service provider associated with this FAS data block.

Coding: See Table B-65.

14 = FAS data block is to be used with GBAS only.

15 = FAS data block can be used with any SBAS service provider.

Note - This parameter is not used for approaches conducted using GBAS or GRAS pseudo-range corrections.

Airport ID: the three- or four-letter designator used to designate an airport.

Coding: Each character is coded using the lower 6 bits of its IA-5 representation. For each character, b_i is transmitted first, and 2 zero bits are appended after b_6 , so that 8 bits are transmitted for each character. Only upper case letters, numeric digits and IA-5 “space” are used. The rightmost character is transmitted first. For a three-character airport ID, the rightmost (first transmitted) character shall be IA-5 “space”.

Runway number: the approach runway number.

Coding: 1 to 36 = runway number

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 217

Note - For heliport and point-in-space operations, the runway number value is the integer nearest to one tenth of the final approach course, except when that integer is zero, in which case the runway number is 36.

Runway letter: the one-letter designator used, as necessary, to differentiate between parallel runways.

Coding: 0 = no letter
1 = R (right)
2 = C (centre)
3 = L (left)

Approach performance designator: the general information about the approach design.

Coding: 0 = GAST A or B
1 = GAST C
2 = GAST C and D
3 = GAST C, GAST D and an additional approach service type to be defined in the future
4 = GAST C, GAST D and two additional approach service type to be defined in the future
5 To 7= Spare

Note - Some airborne equipment designed for Category I performance is insensitive to the value of the APD. It is intended that airborne equipment designed for Category I performance accepts APD values of at least 1-4 as valid to accommodate future extensions to higher performance types using the same FAS data block.

Route indicator: the one-letter identifier used to differentiate between multiple approaches to the same runway end.

Coding: The letter is coded using bits b_1 through b_5 of its IA-5 representation. Bit b_1 is transmitted first. Only upper case letters, excluding “I” and “O”, or IA-5 “space” are used.

Reference path data selector (RPDS): the numeric identifier that is used to select the FAS data block (desired approach).

Note - The RPDS for a given FAS data block is different from every other RPDS and every reference station data selector (RSDS) broadcast on the same frequency by every GBAS within the broadcast region.

Reference path identifier (RPI): the three or four alphanumeric characters used to uniquely designate the reference path.

Coding: Each character is coded using bits b_1 through b_6 of its IA-5 representation. For each character, b_1 is transmitted first, and 2 zero bits are appended after b_6 so that 8 bits are transmitted for each character. Only upper case letters, numeric digits and IA-5 “space” are used. The rightmost character is transmitted first. For a three-character reference path identifier, the rightmost (first transmitted) character shall be IA-5 “space”.

Note - The LTP/FTP is a point over which the FAS path passes at a relative height specified by the TCH. LTP is normally located at the intersection of the runway centerline and the threshold.

LTP/FTP latitude: the latitude of the LTP/FTP point in arc seconds.

Coding: Positive value denotes north latitude.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 218

Negative value denotes south latitude.

LTP/FTP longitude: the longitude of the LTP/FTP point in arc seconds.

Coding: Positive value denotes east longitude.
Negative value denotes west longitude.

LTP/FTP height: the height of the LTP/FTP above the WGS-84 ellipsoid.

Coding: This field is coded as an unsigned fixed-point number with an offset of –512 meters. A value of zero in this field places the LTP/FTP 512 meters below the earth ellipsoid.

Note - The FPAP is a point at the same height as the LTP/FTP that is used to define the alignment of the approach. The origin of angular deviations in the lateral direction is defined to be 305 meters (1 000 ft) beyond the FPAP along the lateral FAS path. For an approach aligned with the runway, the FPAP is at or beyond the stop end of the runway.

Δ FPAP latitude: the difference of latitude of the runway FPAP from the LTP/FTP in arc seconds.

Coding: Positive value denotes the FPAP latitude north of LTP/FTP latitude.
Negative value denotes the FPAP latitude south of the LTP/FTP latitude.

Δ FPAP longitude: the difference of longitude of the runway FPAP from the LTP/FTP in arc seconds.

Coding: Positive value indicates the FPAP longitude east of LTP/FTP longitude.
Negative value indicates the FPAP longitude west of LTP/FTP longitude.

Approach TCH: the height of the FAS path above the LTP/FTP defined in either feet or meters as indicated by the TCH units selector.

Approach TCH units selector: the units used to describe the TCH.

Coding: 0 = feet
1 = meters

Glide path angle (GPA): the angle of the FAS path with respect to the horizontal plane tangent to the WGS-84 ellipsoid at the LTP/FTP.

Course width: the lateral displacement from the path defined by the FAS at the LTP/FTP at which full-scale deflection of a course deviation indicator is attained.

Coding: This field is coded as an unsigned fixed-point number with an offset of 80 meters. A value of zero in this field indicates a course width of 80 meters at the LTP/FTP.

Length offset: the distance from the stop end of the runway to the FPAP.

Coding: 1111 1111 = not provided

Final approach segment CRC: the 32-bit CRC appended to the end of each FAS data block in order to ensure approach data integrity. The 32-bit final approach segment CRC shall be calculated in accordance with 3.9. The length of the CRC code shall be $k = 32$ bits.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 219

The CRC generator polynomial shall be:

$$G(x) = x^{32} + x^{31} + x^{24} + x^{22} + x^{16} + x^{14} + x^8 + x^7 + x^5 + x^3 + x + 1$$

The CRC information field, $M(x)$, shall be:

$$M(x) = \sum_{i=1}^{272} m_i x^{272-i} = m_1 x^{272} + m_2 x^{271} + \dots + m_{272} x^0$$

$M(x)$ shall be formed from all bits of the associated FAS data block, excluding the CRC. Bits shall be arranged in the order transmitted, such that m_1 corresponds to the LSB of the operation type field, and m_{272} corresponds to the MSB of the length offset field. The CRC shall be ordered such that r_1 is the LSB and r_{32} is the MSB.

3.6.4.6 Type 5 message — predicted ranging source availability. When used, the Type 5 message shall contain rising and setting information for the currently visible or soon to be visible ranging sources. Predicted ranging source availability parameters shall be as follows:

Modified Z-count: indicates the time of applicability of the parameters in this message.

Coding: Same as modified Z-count field in Type 1 message (3.6.4.2).

Number of impacted sources: the number of sources for which duration information applicable to all approaches is provided.

Coding: 0 = Only specified obstructed approaches have limitations.
1 to 31 = The number of ranging sources impacted.

Ranging source ID: as for Type 1 message (3.6.4.2).

Source availability sense: indicates whether the ranging source will become available or cease to be available.

Coding: 0 = Differential corrections will soon cease to be provided for the associated ranging source.
1 = Differential corrections will soon start to be provided for the associated ranging source.

Source availability duration: the predicted minimum ranging source availability duration relative to the modified Z-count.

Coding: 111 1111 = The duration is greater than or equal to 1 270 seconds.

Number of obstructed approaches: the number of approaches for which the corrections will be reduced due to approach unique constellation masking.

Reference path data selector: an indication of the FAS data block to which the source availability data applies (3.6.4.5.1).

Number of impacted sources for this approach: the number of sources for which duration information applicable only to this approach is provided.

3.6.4.7 Type 6 Message

Note- Type 6 message is reserved for future use to provide the information required for Category II/III precision approaches.

3.6.4.8 Type 7 Message

Note - Type 7 message is reserved for national applications.

3.6.4.9 Type 8 Message

Note - Type 8 message is reserved for local and regional test applications.

3.6.4.10 Type 101 Message - GRAS Pseudo –Range Corrections

3.6.4.10.1 The Type 101 message shall provide the differential correction data for individual GNSS ranging sources (Table B-70A). The message shall contain three sections:

- a) message information (time of validity, additional message flag, number of measurements and the measurement type);
- b) low-frequency information (ephemeris decorrelation parameter, satellite ephemeris CRC and satellite availability information); and
- c) satellite data measurement blocks.

Note .— All parameters in this message type apply to 100-second carrier-smoothed pseudo-ranges.

3.6.4.10.2 Each Type 101 message shall include ephemeris decorrelation parameter, ephemeris CRC and source availability duration parameters for one satellite ranging source. The ephemeris decorrelation parameter, ephemeris CRC and source availability duration shall apply to the first ranging source in the message.

3.6.4.10.3 Pseudo-range correction parameters shall be as follows:

Modified Z-count: as defined in 3.6.4.2.3.

Additional message flag: as defined in 3.6.4.2.3 except applicable to Type 101 messages.

Number of measurements: as defined in 3.6.4.2.3.

Measurement type: as defined in 3.6.4.2.3.

Ephemeris de correlation parameter (P): as defined in 3.6.4.2.3.

Ephemeris CRC: as defined in 3.6.4.2.3.

Source availability duration: as defined in 3.6.4.2.3.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 221

Number of B parameters: an indication of whether the B parameters are included in the measurement block for each ranging source.

Coding: 0 = B parameters are not included
1 = 4 B parameters per measurement block

3.6.4.10.4 The measurement block parameters shall be as follows:

Ranging source ID: as defined in 3.6.4.2.4.

Issue of data (IOD): as defined in 3.6.4.2.4.

Pseudo-range correction (PRC): as defined in 3.6.4.2.4.

Range rate correction (RRC): as defined in 3.6.4.2.4.

σ_{pr_gnd} : as defined in 3.6.4.2.4, with the exception of the range of values and resolution.

B1 through B4: as defined in 3.6.4.2.4.

Note.— Inclusion of the B parameters in the measurement block is optional for Type 101 messages.

3.6.4.11 TYPE 11 MESSAGE — PSEUDO-RANGE CORRECTIONS — 30-SECOND SMOOTHED PSEUDO-RANGES

3.6.4.11.1 The Type 11 message shall provide the differential correction data for individual GNSS ranging sources (Table B-70B) with 30-second code-carrier smoothing applied. The message shall contain three sections:

- a) message information (time of validity, additional message flag, number of measurements and the measurement type);
- b) low-frequency information (ephemeris decorrelation parameter); and
- c) satellite data measurement blocks.

Note.— Transmission of the low-frequency data for SBAS ranging sources is optional.

3.6.4.11.2 Each Type 11 message shall include the ephemeris decorrelation parameter for one satellite ranging source. The ephemeris decorrelation parameter shall apply to the first ranging source in the message.

Note.— The ephemeris CRC and source availability duration parameters are not included in the Type 11 message because they are provided in the Type 1 message.

3.6.4.11.3 Pseudo-range correction parameters for the Type 11 message shall be as follows:

Modified Z-count: as defined in 3.6.4.2.3.

Additional message flag: an identification of whether the set of measurement blocks in a single frame for a particular measurement type is contained in a single Type 11 message or a linked pair of messages.

Coding: 0 = All measurement blocks for a particular measurement type are contained in one Type 11 message.

1 = This is the first transmitted message of a linked pair of Type 11 messages that together contain the set of all measurement blocks for a particular measurement type.

2 = Spare

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 222

3 = This is the second transmitted message of a linked pair of Type 11 messages that together contain the set of all measurement blocks for a particular measurement type.

Number of measurements: the number of measurement blocks in the message.

Measurement type: as defined in 3.6.4.2.3.

Ephemeris decorrelation parameter D (P_D): a parameter that characterizes the impact of residual ephemeris errors due to decorrelation for the first measurement block in the message.

Note.— This parameter, P_D , may be different than the ephemeris decorrelation parameter P provided in the Type 1 message. Additional information regarding the difference in these parameters is given in Attachment D, 7.5.6.1.3 and 7.5.6.1.4.

For a SBAS geostationary satellite, the ephemeris decorrelation parameter, if transmitted, shall be coded as all zeros.

3.6.4.11.4 The measurement block parameters shall be as follows:

Ranging source ID: as defined in 3.6.4.2.3.

Pseudo-range correction (PRC_{30}): the correction to the ranging source pseudo-range based on 30-second carrier smoothing.

Range rate correction (RRC_{30}): the rate of change of the pseudo-range correction based on 30-second carrier smoothing.

Sigma_PR_gnd_D ($\sigma_{pr_gnd_D}$): the standard deviation of a normal distribution associated with the signal-in-space contribution of the pseudo-range error in the 100-second smoothed correction in the Type 1 message at the GBAS reference point (3.6.5.5.1 and 3.6.7.2.2.4).

Note.— The parameter $\sigma_{pr_gnd_D}$ differs from σ_{pr_gnd} for the corresponding measurement in the Type 1 message in that $\sigma_{pr_gnd_D}$ should include no inflation to address overbounding of decorrelated ionospheric errors.

Coding: 1111 1111 = Ranging source correction invalid.

Sigma_PR_gnd_30s ($\sigma_{pr_gnd_30}$): the standard deviation of a normal distribution that describes the nominal accuracy of corrected pseudo-range smoothed with a time constant of 30 seconds at the GBAS reference point.

Note.— The normal distribution $N(0, \sigma_{pr_gnd_30})$ is intended to be an appropriate description of the errors to be used in optimizing the weighting used in a weighted least squares position solution. The distribution need not bound the errors as described in 3.6.5.5.1 and 3.6.7.2.2.4.

Coding: 1111 1111 = Ranging source correction invalid.

3.6.5 Definitions of Protocols for data application

Note - This section defines the inter-relationships of the data broadcast message parameters. It provides definitions of parameters that are not transmitted, but are used by either or both non-aircraft and aircraft elements, and that define terms applied to determine the navigation solution and its integrity.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 223

3.6.5.1 Measured and carrier smoothed pseudo-range. The broadcast correction is applicable to carrier smoothed code pseudo-range measurements that have not had the satellite broadcast troposphere and ionosphere corrections applied to them. The carrier smoothing is defined by the following filter

$$P_{CSCn} = \alpha P + (1 - \alpha) \left(P_{CSCn-1} + \frac{\lambda}{2\pi} (\phi_n - \phi_{n-1}) \right)$$

where

- P_{CSCn} = the smoothed pseudo-range;
- P_{CSCn-1} = the previous smoothed pseudo-range;
- P = the raw pseudo-range measurement where the raw pseudo-range measurements are obtained from a carrier driven code loop, first order or higher and with a one-sided noise bandwidth greater than or equal to 0.125 Hz;
- λ = the L1 wavelength;
- ϕ_n = the carrier phase;
- ϕ_{n-1} = the previous carrier phase; and
- α = the filter weighting function equal to the sample interval divided by the smoothing time constant. For GBAS pseudo-range corrections in message Type 1 and message Type 101, the smoothing time constant is 100 seconds, except as specified in 3.6.8.3.5.1 for airborne equipment. For GBAS pseudo-range corrections in message Type 11, the smoothing time constant is 30 seconds.

3.6.5.2 *Corrected pseudo-range*. The corrected pseudo-range for a given satellite at time t is:

$$PR_{corrected} = P_{CSC} + PRC + RRC \times (t - tz - count) + TC + c \times (\Delta t_{sv})_{L1}$$

where

- P_{CSC} = the smoothed pseudo-range (defined in 3.6.5.1);
- PRC = the pseudo-range correction from the appropriate message:
 - a) for 100-second smoothed pseudo-ranges, PRC is taken from message Type 1 or Type 101 defined in 3.6.4.2; and
 - b) for 30-second smoothed pseudo-ranges, PRC is PRC30 taken from message Type 11 defined in 3.6.4.11;
- RRC = the pseudo-range correction rate from the appropriate message:
 - a) for 100-second smoothed pseudo-ranges, RRC is taken from message Type 1 or Type 101 defined in 3.6.4.2; and
 - b) for 30-second smoothed pseudo-ranges, RRC is RRC30 taken from message Type 11 defined in 3.6.4.11;
- t = the current time;
- tz -count = the time of applicability derived from the modified Z-count of the message containing PRC and RRC;
- TC = the tropospheric correction (defined in 3.6.5.3); and
- c and $(\Delta t_{sv})_{L1}$ are as defined in 3.1.2.2 for GPS satellites.

3.6.5.3 Tropospheric Delay

3.6.5.3.1 The tropospheric correction for a given satellite is:

$$TC = N_r h_0 \frac{10^{-6}}{\sqrt{0.002 + \sin^2(EI_i)}} (1 - e^{-\Delta h/h_0})$$

Where

N_r = refractivity index from the Type 2 message (3.6.4.3);

Δh = height of the aircraft above the GBAS reference point;

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 224

Eli = elevation angle of the ith satellite; and

h0 = troposphere scale height from the Type 2 message.

3.6.5.3.2 The residual tropospheric uncertainty is:

$$\sigma_{tropo} = \sigma_n h_0 \frac{10^{-6}}{\sqrt{0.002 + \sin^2(EI_i)}} (1 - e^{-\Delta h/h_0})$$

where σ_n = the refractivity uncertainty from the Type 2 message (3.6.4.3).

3.6.5.4 Residual ionospheric uncertainty. The residual ionospheric uncertainty for a given satellite is:

$$\sigma_{iono} = F_{pp} \times \sigma_{vert_iono_gradient} \times (x_{air} + 2 \times \tau \times v_{air})$$

where

F_{pp} = the vertical-to-slant obliquity factor for a given satellite (3.5.5.2);

$\sigma_{vert_iono_gradient}$ = (as defined in 3.6.4.3);

x_{air} = the distance (slant range) in metres between current aircraft location and the GBAS reference point indicated in the Type 2 message;

τ = 100 seconds (time constant used in 3.6.5.1); and

v_{air} = the aircraft horizontal approach velocity (metres per second).

3.6.5.5 Protection Levels

3.6.5.5.1 *Protection levels for all GBAS approach service types.* The signal-in-space vertical and lateral protection levels (VPL and LPL) are upper confidence bounds on the error in the position relative to the GBAS reference point defined as:

$$VPL = \text{MAX}\{VPL_{H0}, VPL_{H1}\}$$

$$LPL = \text{MAX}\{LPL_{H0}, LPL_{H1}\}$$

3.6.5.5.1.1 Normal measurement

3.6.5.5.1.1.1 The vertical protection level (VPL_{H0}) and lateral protection level (LPL_{H0}), assuming that normal measurement conditions (i.e. no faults) exist in all reference receivers and on all ranging sources, is calculated as:

$$VPL_{H0} = K_{ffmd\text{vert}} + DV$$

$$LPL_{H0} = K_{ffmd\text{lat}} + DL$$

where

$$\sigma_{\text{vert}} = \sqrt{\sum_{i=1}^N s_{\text{vert}_i}^2 \times \sigma_i^2}$$

$$\sigma_{\text{lat}} = \sqrt{\sum_{i=1}^N s_{\text{lat}_i}^2 \times \sigma_i^2}$$

$$\sigma_i^2 = \sigma_{\text{pr_gnd},i}^2 + \sigma_{\text{tropo},i}^2 + \sigma_{\text{pr_air},i}^2 + \sigma_{\text{iono},i}^2;$$

and

$\sigma_{\text{pr_gnd},i}$ is dependent on the active GAST.

For GAST A, B or C: $\sigma_{\text{pr_gnd},i} = \sigma_{\text{pr_gnd}}$ for the i^{th} ranging source as defined in 3.6.4.2;

For GAST D: $\sigma_{\text{pr_gnd},i} = \sigma_{\text{pr_gnd}_D}$ for the i^{th} ranging source (3.6.4.11);

$\sigma_{\text{tropo},i}$, $\sigma_{\text{pr_air},i}$ and $\sigma_{\text{iono},i}$ are as defined in 3.6.5.5.1.1.2;

K_{ffmd} = the multiplier derived from the probability of fault-free missed detection;

s_{vert_i} = $s_{v,i} + s_{x,i} \times \tan(\text{GPA})$;

s_{lat_i} = $s_{y,i}$;

$s_{x,i}$ = the partial derivative of position error in the x-direction with respect to pseudo-range error on the i^{th} satellite;

$s_{y,i}$ = the partial derivative of position error in the y-direction with respect to pseudo-range error on the i^{th} satellite;

$s_{v,i}$ = the partial derivative of position error in the vertical direction with respect to pseudo-range error on the i^{th} satellite;

GPA = the glidepath angle for the final approach path (3.6.4.5.1);

N = the number of ranging sources used in the position solution; and

i = the ranging source index for ranging sources used in the position solution;

DV = an airborne determined parameter depending on the active GAST.

For GAST A, B or C: DV = 0;

For GAST D: DV is calculated as the magnitude of the vertical projection of the difference between the 30-second and 100-second position solutions;

DL = an airborne determined parameter depending on the active GAST.

For GAST A, B or C: DL = 0;

For GAST D: DL is calculated as the magnitude of the lateral projection of the difference between the 30-second and 100-second position solutions.

Note 1.— The airborne 30-second and 100-second position solutions, DV and DL are defined in RTCA MOPS DO-253D.

Note 2.— The coordinate reference frame is defined such that x is along track positive forward, y is crosstrack positive left in the local level tangent plane and v is the positive up and orthogonal to x and y.

3.6.5.5.1.1.2 For a general-least-squares position solution, the projection matrix S is defined as;

$$S \equiv \begin{bmatrix} S_{x,1} & S_{x,2} & \cdots & S_{x,N} \\ S_{y,1} & S_{y,2} & \cdots & S_{y,N} \\ S_{v,1} & S_{v,2} & \cdots & S_{v,N} \\ S_{t,1} & S_{t,2} & \cdots & S_{t,N} \end{bmatrix} = (G^T \times W \times G)^{-1} \times G^T \times W$$

where

$$G_i = [-\cos El_i \cos Az_i \quad -\cos El_i \sin Az_i \quad -\sin El_i \quad 1] = i^{\text{th}} \text{ row of } G; \text{ and}$$

$$W = \begin{bmatrix} \sigma_{w,1}^2 & 0 & \cdots & 0 \\ 0 & \sigma_{w,2}^2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \sigma_{w,N}^2 \end{bmatrix}^{-1}$$

$$\text{where } \sigma_{w,i}^2 = \sigma_{pr_gnd,i}^2 + \sigma_{tropo,i}^2 + \sigma_{pr_air,i}^2 + \sigma_{iono,i}^2;$$

where

$\sigma_{pr_gnd,i}$ = is dependent on the active GAST.

For GAST A, B or C or the GBAS positioning service: $\sigma_{pr_gnd,i} = \sigma_{pr_gnd}$ for the i^{th} ranging source as defined in (3.6.4.2);

For GAST D: $\sigma_{pr_gnd,i} = \sigma_{pr_gnd,30}$ for the i^{th} ranging source (3.6.4.11);

$\sigma_{tropo,i}$ = the residual tropospheric uncertainty for the i^{th} ranging source (3.6.5.3);

$\sigma_{iono,i}$ = the residual ionospheric delay (due to spatial decorrelation) uncertainty for the i^{th} ranging source (3.6.5.4); and

$\sigma_{pr_air,i} = \sqrt{\sigma_{receiver}^2(El_i) + \sigma_{multipath}^2(El_i)}$, the standard deviation of the aircraft contribution to the corrected pseudo range error for the i^{th} ranging source. The total aircraft contribution includes the receiver contribution (3.6.8.2.1) and a standard allowance for airframe multipath;

where

$\sigma_{multipath}(El_i) = 0.13 + 0.53e^{-El_i/10 \text{ deg}}$, the standard model for the contribution of airframe multipath (in metres);

El_i = the elevation angle for the i^{th} ranging source (in degrees); and

Az_i = the azimuth for the i^{th} ranging source taken counterclockwise for the x axis (in degrees).

3.6.5.5.1.2 Faulted measurement conditions. When the Type 101 message is broadcast without B parameter blocks, the values for VPL_{H1} and LPL_{H1} are defined as zero. Otherwise, the vertical protection level (VPL_{H1}) and lateral protection level (LPL_{H1}), assuming that a latent fault exists in one, and only one reference receiver, are:

$$VPL_{H1} = \max [VPL_j] + D_v$$

$$LPL_{H1} = \max [LPL_j] + D_L$$

where VPL_j and LPL_j for $j = 1$ to 4 are

$VPL_j = |B_vert_j| + K_{md} \sigma_{vert,H1}$; and

$LPL_j = |B_lat_j| + K_{md} \sigma_{lat,H1}$;

D_v = an airborne determined parameter depending on the active GAST (3.6.5.5.1.1.1);

D_L = an airborne determined parameter depending on the active GAST (3.6.5.5.1.1.1);

and

- $B_{vertj} = \sum_{i=1}^N (s_{verti} \times B_{ij});$
 $B_{latj} = \sum_{i=1}^N (s_{lati} \times B_{ij});$
 B_{ij} = the broadcast differences between the broadcast pseudo-range corrections and the corrections obtained excluding the j^{th} reference receiver measurement for the i^{th} ranging source;
 K_{md} = the multiplier derived from the probability of missed detection given that the ground subsystem is faulted;
 $\sigma_{vert,H1}^2 = \sum_{i=1}^N (s_{verti}^2 \times \sigma_{H1i}^2);$
 $\sigma_{lat,H1}^2 = \sum_{i=1}^N (s_{lati}^2 \times \sigma_{H1i}^2);$
 $\sigma_{H1i}^2 = \left(\frac{M_i}{U_i}\right) \sigma_{pr_gnd,i}^2 + \sigma_{pr_air,i}^2 + \sigma_{tropo,i}^2 + \sigma_{iono,i}^2;$
 $\sigma_{pr_gnd,i}$ is dependent on the active GAST.
 For GAST A, B or C: $\sigma_{pr_gnd,i} = \sigma_{pr_gnd}$ for the i^{th} ranging source as defined in (3.6.4.2);
 For GAST D: $\sigma_{pr_gnd,i} = \sigma_{pr_gnd_D}$ for the i^{th} ranging source (3.6.4.11);
 $\sigma_{tropo,i}^2$, $\sigma_{pr_air,i}^2$ and $\sigma_{iono,i}^2$ are as defined in 3.6.5.5.1.1.2;
 M_i = the number of reference receivers used to compute the pseudo-range corrections for the i^{th} ranging source (indicated by the B values); and
 U_i = the number of reference receivers used to compute the pseudo-range corrections for the i^{th} ranging source, excluding the j^{th} reference receiver.

Note.— A latent fault includes any erroneous measurement(s) that is not immediately detected by the ground subsystem, such that the broadcast data are affected and there is an induced position error in the aircraft subsystem.

3.6.5.5.1.3 Definition of K multipliers for GBAS approach services. The multipliers are given in Table B-135.

Table B-135. K-multipliers for GBAS approach services

Multiplier	M_i			
	<i>1</i> <small>(Note)</small>	2	3	4
K_{ffmd}	6.86	5.762	5.81	5.847
K_{md}	Not used	2.935	2.898	2.878

Note.— For GAST A supported by Type 101 messages broadcast without the B parameter block.

3.6.5.5.2 GBAS positioning service. The signal-in-space horizontal protection level is an upper confidence bound on the horizontal error in the position relative to the GBAS reference point defined as:

$$HPL = \text{MAX}\{HPL_{H0}, HPL_{H1}, HEB\}$$

3.6.5.5.2.1 Normal measurements conditions. The horizontal protection level (HPL_{H0}), assuming that normal measurement conditions (i.e. no faults) exist in all reference receivers and on all ranging sources, is calculated as:

$$HPL_{H0} = K_{\text{fmd, POS}} d_{\text{major}}$$

where:

$$d_{\text{major}} = \sqrt{\frac{d_x^2 + d_y^2}{2} + \sqrt{\left(\frac{d_x^2 - d_y^2}{2}\right)^2 + d_{xy}^2}}$$

$$d_x^2 = \sum_{i=1}^N s_{x,i}^2 \sigma_i^2$$

$$d_y^2 = \sum_{i=1}^N s_{y,i}^2 \sigma_i^2$$

$$d_{xy} = \sum_{i=1}^N s_{x,i} s_{y,i} \sigma_i^2$$

- $s_{x,i}$ = the partial derivative of position error in the x-direction with respect to pseudo-range error on the i^{th} satellite
- $s_{y,i}$ = the partial derivative of position error in the y-direction with respect to pseudo-range error on the i^{th} satellite
- $K_{\text{fmd, POS}}$ = the multiplier derived from the probability of fault-free missed detection
- N = the number of ranging sources used in the position solution
- i = the ranging source index for ranging sources used in the position solution
- σ_i = the pseudo-range error term as defined in 3.6.5.5.1.1

Note.— For the GBAS positioning service, the x and y axes define an arbitrary orthogonal basis in the horizontal plane.

3.6.5.5.2.2 Faulted measurement conditions. When the Type 101 message is broadcast without B parameter blocks, the value for HPL_{H1} is defined as zero. Otherwise, the horizontal protection level (HPL_{H1}), assuming that a latent fault exists in one and only one reference receiver, is:

$$HPL_{H1} = \text{MAX}[HPL_j]$$

where HPL_j for $j = 1$ to 4

$$HPL_j = |B_{\text{horz}_j}| + K_{\text{mod_POS}} d_{\text{major}, H1}$$

and

$$B_{\text{horz}_j} = \sqrt{\left(\sum_{i=1}^N s_{x,i} B_{i,j}\right)^2 + \left(\sum_{i=1}^N s_{y,i} B_{i,j}\right)^2}$$

$B_{i,j}$ = the broadcast differences between the broadcast pseudo-range corrections and the corrections obtained excluding the j^{th} reference receiver measurement for the i^{th} ranging source.
 $K_{\text{mod_pos}}$ = the multiplier derived from the probability of missed detection given that the ground subsystem is faulted.

$$d_{\text{major}, H1} = \sqrt{\frac{d_{H1x}^2 + d_{H1y}^2}{2} + \left(\frac{d_{H1x}^2 - d_{H1y}^2}{2}\right)^2 + d_{H1xy}^2}$$

$$d_{H1x}^2 = \sum_{i=1}^N s_{x,i}^2 \sigma_{H1i}^2$$

$$d_{H1y}^2 = \sum_{i=1}^N s_{y,i}^2 \sigma_{H1i}^2$$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 229

$$d_{H1_{xy}^2} = \sum_{i=1}^N s_{x,i} s_{y,i}^2 \sigma_{H1_i^2}$$

Note.— For the GBAS positioning service, the x and y axes define an arbitrary orthogonal basis in the horizontal plane.

$$\sigma_{H1_i^2} = \left(\frac{M_i}{U_i}\right) \sigma_{pr_gnd,i}^2 + \sigma_{pr_air,i}^2 + \sigma_{tropo,i}^2 + \sigma_{iono,i}^2$$

M_i = the number of reference receivers used to compute the pseudo-range corrections for the i^{th} ranging source (indicated by the B values).

U_i = the number of reference receivers used to compute the pseudo-range corrections for the i^{th} ranging source, excluding the j^{th} reference receiver.

Note.— A latent fault includes any erroneous measurement(s) that is not immediately detected by the ground subsystem, such that the broadcast data are affected and there is an induced position error in the aircraft subsystem.

3.6.5.5.2.3 Definition of K multipliers for GBAS positioning service. The multiplier $K_{\text{ffmd_POS}}$ is equal to 10.0 and the multiplier $K_{\text{md_POS}}$, is equal to 5.3.

3.6.5.6 Alert Limits

Note 1- Guidance concerning the calculation of alert limits, including approaches associated with channel numbers 40 000 to 99 999, is provided in Attachment D, 7.13.

Note 2. — Computation of alert limits depends on the active service type.

3.6.5.6.1 *GAST C and D alert limits.* The alert limits are defined in Tables B-68 and B-69. For aircraft positions at which the lateral deviation exceeds twice the deviation at which full-scale lateral deflection of a course deviation indicator is achieved, or vertical deviation exceeds twice the deviation at which full-scale fly-down deflection of a course deviation indicator is achieved, both the lateral and vertical alert limits are set to the maximum values given in the tables.

3.6.5.6.2 *GAST A and B alert limits.* The alert limits are equal to the FASLAL and FASVAL taken from the Type 4 message for approaches with channel numbers in the range of 20 001 to 39 999. For approaches with channel numbers in the range 40 000 to 99 999, the alert limits are stored in the on-board database.

3.6.5.7 Channel number. Each GBAS approach transmitted from the ground subsystem is associated with a channel number in the range of 20 001 to 39 999. If provided, the GBAS positioning service is associated with a separate channel number in the range of 20 001 to 39 999. The channel number is given by:

$$\text{Channel number} = 20\,000 + 40(F - 108.0) + 411(S)$$

where

F = the data broadcast frequency (MHz)

S = RPDS or RSDS

and

RPDS = the reference path data selector for the FAS data block (as defined in 3.6.4.5.1)

RSDS = the reference station data selector for the GBAS ground subsystem (as defined in 3.6.4.3.1)

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

Table B-136. GAST C and D lateral alert limit

Horizontal distance of aircraft position from the LTP/FTP as translated along the final approach path (metres)	Lateral alert limit (metres)
$D \leq 873$	FASLAL
$873 < D \leq 7\ 500$	$0.0044D \text{ (m)} + \text{FASLAL} - 3.85$
$D > 7\ 500$	$\text{FASLAL} + 29.15$

Table B-137. GAST C and D vertical alert limit

Height above LTP/FTP of aircraft position translated onto the final approach path (feet)	Vertical alert limit (metres)
$H \leq 200$	FASVAL
$200 < H \leq 1\ 340$	$0.02925H \text{ (ft)} + \text{FASVAL} - 5.85$
$H > 1\ 340$	$\text{FASVAL} + 33.35$

For channel numbers transmitted in the additional data block 2 of Type 2 message (as defined in 3.6.4.3.2.1), only RSDS are used.

Note 1 - When the FAS is not broadcast for an approach supported by GAST A or B, the GBAS approach is associated with a channel number in the range 40 000 to 99 999.

Note 2 - Guidance material concerning channel number selection is provided in Attachment D, 7.7.

3.6.5.8 Ephemeris Error Position Bound

Note - Ephemeris error position bounds are computed only for core satellite constellation ranging sources used in the position solution (j index) and not for other types of ranging sources (SBAS satellites or pseudolites) that are not subject to undetected ephemeris failures. However, the calculations of these position bounds use information from all ranging sources used in the position solution (i index).

3.6.5.8.1 GBAS approach. The vertical and lateral ephemeris error position bounds are defined as:

$$\text{VEB} = \text{MAX}_j \{ \text{VEB}_j \} + D_v$$

$$\text{LEB} = \text{MAX}_j \{ \text{LEB}_j \} + D_L$$

The vertical and lateral ephemeris error position bounds for the j^{th} core satellite constellation ranging source used in the position solution are given by:

$$\text{VEB}_j = |s_{\text{vert}_j}| x_{\text{air}P_{ej}} + K_{\text{md}_{ej}} \sqrt{\sum_{i=1}^N s_{\text{vert}_i}^2 \times \sigma_i^2}$$

$$\text{LEB}_j = |s_{\text{lat}_j}| x_{\text{air}P_{ej}} + K_{\text{md}_{ej}} \sqrt{\sum_{i=1}^N s_{\text{lat}_i}^2 \times \sigma_i^2}$$

where:

D_V = an airborne determined parameter depending on the active GAST (3.6.5.5.1.1.1);
 D_L = an airborne determined parameter depending on the active GAST (3.6.5.5.1.1.1);
 $s_{vert\ i\ or\ j}$ is defined in 3.6.5.5.1.1.1;

$s_{lat\ i\ or\ j}$ is defined in 3.6.5.5.1.1.1;
 x_{air} is defined in 3.6.5.4;
 N is the number of ranging sources used in the position solution;
 σ_i is defined in 3.6.5.5.1.1.1;
 P_{ej} is the broadcast ephemeris decorrelation parameter for the j^{th} ranging source. The source of this parameter depends on the active GBAS approach service type:
 GAST A, B or C: $P_{ej} = P$ from the Type 1 or Type 101 Message corresponding to the j^{th} ranging source. (3.6.4.2.3);
 GAST D: $P_{ej} = P_D$ from the Type 11 Message corresponding to the j^{th} ranging source (3.6.4.11.3);
 K_{md_ej} is the broadcast ephemeris missed detection multiplier for GAST A-C associated with the satellite constellation for the j^{th} ranging source. The source of this parameter depends on the active GBAS approach service type:
 GAST A, B or C: $K_{md_ej} = K_{md_e,GPS}$ or $K_{md_e,GLONASS}$ as obtained from the Type 2 Message Additional Data block 1 (3.6.4.3.1);
 GAST D: $K_{md_ej} = K_{md_e_D,GPS}$ or $K_{md_e_D,GLONASS}$ as obtained from the Type 2 Message Additional Data block 3 (3.6.4.3.2.2).

3.6.5.8.2 GBAS positioning service. The horizontal ephemeris error position bound is defined as:

$$HEB = \text{MAX}_j \{HEB_j\}$$

The horizontal ephemeris error position bound for the j^{th} core satellite constellation ranging source used in the position solution is given by:

$$HEB_j = |s_{horz,j}| x_{air} P_j + K_{md_e_POS} d_{major}$$

where:

$s_{horz,j}^2 = s_{xj}^2 + s_{yj}^2$
 s_{xj} is as defined in 3.6.5.5.2.1
 s_{yj} is as defined in 3.6.5.5.2.1
 x_{air} is defined in 3.6.5.4
 P_j is the broadcast ephemeris decorrelation parameter for the j^{th} ranging source. The source of this parameter does not depend on the active GBAS approach service type. In all cases, $P_j = P$ from the Type 1 or Type 101 Message (3.6.4.2.3) corresponding to the j^{th} ranging source.
 $K_{md_e_POS}$ is the broadcast ephemeris missed detection multiplier for the GBAS positioning service associated with the satellite constellation for the j^{th} ranging source ($K_{md_e_POS,GPS}$ or $K_{md_e_POS,GLONASS}$)
 d_{major} is as defined in 3.6.5.5.2.1

3.6.5.9 Ionospheric gradient error

$$E_{IG} = Y_{EIG} + M_{EIG} \times D_{EIG}$$

where

Y_{EIG} = maximum value of E_{IG} (metres) in the Type 2 message;

M_{EIG} = slope of maximum E_{IG} (m/km) in the Type 2 message;
 D_{EIG} = the distance in kilometres between the LTP location for the selected approach broadcast in the Type 4 Message and the GBAS reference point in the Type 2 message.

3.6.6 Message Tables

Each GBAS message shall be coded in accordance with the corresponding message format defined in Tables B-70 through B-144.

Note - Message type structure is defined in 3.6.4.1.

Table B-138. Type 1 pseudo-range corrections message

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
Modified Z-count	14	0 to 1 199.9 s	0.1 s
Additional message flag	2	0 to 3	1
Number of measurements (N)	5	0 to 18	1
Measurement type	3	0 to 7	1
Ephemeris decorrelation parameter (P)	8	0 to 1.275×10^{-3} m/m	5×10^{-6} m/m
Ephemeris CRC	16	—	—
Source availability duration	8	0 to 2 540 s	10 s
For N measurement blocks			
Ranging source ID	8	1 to 255	1
Issue of data (IOD)	8	0 to 255	1
Pseudo-range correction (PRC)	16	± 327.67 m	0.01 m
Range rate correction (RRC)	16	± 32.767 m/s	0.001 m/s
σ_{pr_gnd}	8	0 to 5.08 m	0.02 m
B ₁	8	± 6.35 m	0.05 m
B ₂	8	± 6.35 m	0.05 m
B ₃	8	± 6.35 m	0.05 m
B ₄	8	± 6.35 m	0.05 m

Table B-139. Type 101 GRAS pseudo-range corrections message

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
Modified Z-count	14	0 to 1 199.9 s	0.1 s
Additional message flag	2	0 to 3	1
Number of measurements (N)	5	0 to 18	1
Measurement type	3	0 to 7	1
Ephemeris decorrelation parameter (P)	8	0 to 1.275×10^{-3} m/m	5×10^{-6} m/m
Ephemeris CRC	16	—	—
Source availability duration	8	0 to 2540 s	10 s
Number of B parameters	1	0 or 4	—
Spare	7	—	—
For N measurement blocks			
Ranging source ID	8	1 to 255	1
Issue of data (IOD)	8	0 to 255	1
Pseudo-range correction (PRC)	16	± 327.67 m	0.01 m
Range rate correction (RRC)	16	± 32.767 m/s	0.001 m/s
σ_{pr_gnd}	8	0 to 50.8 m	0.2 m
B parameter block (if provided)			
B ₁	8	± 25.4 m	0.2 m
B ₂	8	± 25.4 m	0.2 m
B ₃	8	± 25.4 m	0.2 m
B ₄	8	± 25.4 m	0.2 m

Table B-140. Type 11 pseudo-range corrections (30-second smoothed pseudo-ranges) message

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
Modified Z-count	14	0 – 1199.9 sec	0.1 sec
Additional message flag	2	0 – 3	1
Number of measurements	5	0 – 18	1
Measurement type	3	0 – 7	1
Ephemeris decorrelation parameter D (P _D) (Notes 1, 3)	8	0 – 1.275×10^{-3} m/m	5×10^{-6} m/m
For N measurement blocks:			
Ranging source ID	8	1 – 255	1
Pseudo-range correction (PRC ₃₀)	16	± 327.67 m	0.01 m
Range rate correction (RRC ₃₀)	16	± 32.767 m/s	0.001 m/s
Sigma_PR_gnd_D ($\sigma_{pr_gnd_D}$) (Note 2)	8	0 – 5.08 m	0.02 m
Sigma_PR_gnd_30 ($\sigma_{pr_gnd_30}$) (Note 2)	8	0 – 5.08 m	0.02 m

Notes:

1. For SBAS satellites, the parameter is set to all zeros.
2. 1111 1111 indicates the source is invalid.
3. Parameter is associated with the first transmitted measurement block.

Table B-141. Type 2 GBAS-related data message

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
GBAS reference receivers	2	2 to 4	—
Ground accuracy designator letter	2	—	—
Spare	1	—	—
GBAS continuity/integrity designator	3	0 to 7	1
Local magnetic variation	11	±180°	0.25°
Reserved and set to zero (00000)	5	—	—
$\sigma_{\text{vert_iono_gradient}}$	8	0 to 25.5×10^{-6} m/m	0.1×10^{-6} m/m
Refractivity index	8	16 to 781	3
Scale height	8	0 to 25 500 m	100 m
Refractivity uncertainty	8	0 to 255	1
Latitude	32	±90.0°	0.0005 arcsec
Longitude	32	±180.0°	0.0005 arcsec
GBAS reference point height	24	±83 886.07 m	0.01 m
Additional data block 1 (if provided)			
Reference station data selector	8	0 to 48	1
Maximum use distance (D_{max})	8	2 to 510 km	2 km
$K_{\text{md_e_POS,GPS}}$	8	0 to 12.75	0.05
$K_{\text{md_e,GPS}}$	8	0 to 12.75	0.05
$K_{\text{md_e_POS,GLONASS}}$	8	0 to 12.75	0.05
$K_{\text{md_e,GLONASS}}$	8	0 to 12.75	0.05
Additional data blocks (repeated for all provided)			
Additional data block length	8	2 to 255	1
Additional data block number	8	2 to 255	1
Additional data parameters	Variable	—	—

Table B-142. Type 3 null message

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
Filler	Variable (Note)	N/A	N/A

Note.— The number of bytes in the filler field is 10 less than the message length field in the message header as defined in 3.6.3.4.

Table B-143. Type 4 FAS data message

<i>Data content</i>	<i>Bits used</i>	<i>Range of values</i>	<i>Resolution</i>
For N data sets			
Data set length	8	2 to 212	1 byte
FAS data block	304	—	—
FAS vertical alert limit/approach status	8		
(1) when associated approach performance designator (APD) is coded as 0		0 to 50.8 m	0.2 m
(2) when associated approach performance designator (APD) is not coded as 0		0 to 25.4 m	0.1 m
FAS lateral alert limit/approach status	8	0 to 50.8 m	0.2 m

Table B-144. Type 5 predicted ranging source availability message

Source availability duration	7	0 to 1 270 s	10 s

3.6.7 Non-aircraft elements

3.6.7.1 Performance

3.6.7.1.1 Accuracy

3.6.7.1.1.1 The root-mean-square (RMS) (1 sigma) of the ground subsystem contribution to the corrected 100-second smoothed pseudo-range accuracy for GPS and GLONASS satellites shall be:

$$RMS_{pr_gnd} \leq \sqrt{\frac{(a_0 + a_1 e^{-\theta_n/\theta_0})^2}{M} + (a_2)^2}$$

where

- M = the number of GNSS reference receivers, as indicated in the Type 2 message parameter (3.6.4.3), or, when this parameter is coded to indicate “not applicable”, the value of M is defined as 1;
- n = nth ranging source;
- θ_n = elevation angle for the nth ranging source; and
- $a_0, a_1, a_2,$ and θ_0 = parameters defined in Tables B-72 and B-73 for each of the defined ground accuracy designators (GADs).

Note 1.— The GBAS ground subsystem accuracy requirement is determined by the GAD letter and the number of reference receivers.

Note 2.— The ground subsystem contribution to the corrected 100-second smoothed pseudo-range error specified by the curves defined in Tables B-72 and B-73 and the contribution to the SBAS satellites do not include aircraft noise and aircraft multipath.

Table B-145. GBAS — GPS accuracy requirement parameters

Ground accuracy designator letter	θ_n (degrees)	a_0 (metres)	a_1 (metres)	θ_0 (degrees)	a_2 (metres)
A	≥ 5	0.5	1.65	14.3	0.08
B	≥ 5	0.16	1.07	15.5	0.08
C	> 35	0.15	0.84	15.5	0.04
	5 to 35	0.24	0	—	0.04

Table B-146. GBAS — GLONASS accuracy requirement parameters

Ground accuracy designator letter	θ_n (degrees)	a_0 (metres)	a_1 (metres)	θ_0 (degrees)	a_2 (metres)
A	≥ 5	1.58	5.18	14.3	0.078
B	≥ 5	0.3	2.12	15.5	0.078
C	> 35	0.3	1.68	15.5	0.042
	5 to 35	0.48	0	—	0.042

3.6.7.1.1.2 The RMS of the ground subsystem contribution to the corrected 100-second smoothed pseudo-range accuracy for SBAS satellites shall be:

$$RMS_{pr_gnd} \leq \frac{1.8}{\sqrt{M}} \text{ (metres)}$$

where M is as defined in 3.6.7.1.1.1.

Note - GAD classifications for SBAS ranging sources are under development.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 237

3.6.7.1.2 Integrity

3.6.7.1.2.1 GBAS ground subsystem integrity risk

3.6.7.1.2.1.1 Ground subsystem integrity risk for GBAS approach services

3.6.7.1.2.1.1.1 *Ground subsystem signal-in-space integrity risk for GBAS approach service types A, B or C.* For a GBAS ground subsystem classified as FAST A, B or C, the integrity risk shall be less than 1.5×10^{-7} per approach.

Note 1 - The integrity risk assigned to the GBAS ground subsystem is a subset of the GBAS signal-in-space integrity risk, where the protection level integrity risk (3.6.7.1.2.2.1) has been excluded and the effects of all other GBAS, SBAS and core satellite constellations failures are included. The GBAS ground subsystem integrity risk includes the integrity risk of satellite signal monitoring required in 3.6.7.3.3

Note 2 - GBAS signal-in-space integrity risk is defined as the probability that the ground subsystem provides information which when processed by a fault-free receiver, using any GBAS data that could be used by the aircraft in service volume, results in an out-of-tolerance lateral or vertical relative position error without annunciation for a period longer than the maximum signal in space time-to-alert. An out-of-tolerance lateral or vertical relative position error is defined as an error that exceeds the GBAS approach protection level and, if additional data block 1 is broadcast, the ephemeris error position bound.

3.6.7.1.2.1.1.2 *Ground subsystem signal-in-space integrity risk for GBAS approach service type D.* For a GBAS ground subsystem classified as FAST D the integrity risk for all effects other than errors induced by anomalous ionospheric conditions shall be less than 1.5×10^{-7} per approach.

Note 1.— The integrity risk assigned to the GBAS ground subsystem classified as FAST D is a subset of the GBAS signal-in-space integrity risk, where the protection level integrity risk (3.6.7.1.2.2.1) has been excluded and the effects of all other GBAS, SBAS and core satellite constellations failures are included.

Note 2.— For GAST D the GBAS signal-in-space integrity risk is defined as the probability that the ground subsystem provides information which when processed by a fault-free receiver, using any GBAS data that could be used by the aircraft in the service volume, in the absence of an ionospheric anomaly results in an out-of-tolerance lateral or vertical relative position error without annunciation for a period longer than the maximum signal-in-space time-to-alert. An out-of-tolerance lateral or vertical relative position error is defined as an error that exceeds the GBAS approach services protection level and the ephemeris error position bound. For GAST D, out of tolerance conditions caused by anomalous ionospheric errors are excluded from this integrity risk as the risk due to ionospheric anomalies has been allocated to and is mitigated by the airborne segment.

3.6.7.1.2.1.1.3 *Ground subsystem integrity risk for GAST D.* For a GBAS ground subsystem classified as FAST D, the probability that the ground subsystem internally generates and transmits non-compliant information for longer than 1.5 seconds shall be less than 1×10^{-9} in any one landing.

Note 1.— This additional integrity risk requirement assigned to FAST D GBAS ground subsystems is defined in terms of the probability that internal ground subsystem faults generate non-compliant information. Non-compliant information in this context is defined in terms of the intended function of the ground subsystem to support landing operations in Category III minima. For example, non-compliant information includes any broadcast signal or broadcast information that is not monitored in accordance with the standard.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 238

Note 2.— Environmental conditions (anomalous ionosphere, troposphere, radio frequency interference, GNSS signal multipath, etc.) are not considered faults; however, faults in ground subsystem equipment used to monitor for or mitigate the effects of these environmental conditions are included in this requirement. Similarly, the core satellite constellation ranging source faults are excluded from this requirement; however, the ground subsystem’s capability to provide integrity monitoring for these ranging sources is included. Monitoring requirements for ranging source faults and ionosphere environmental conditions are separately specified in 3.6.7.3.3.2, 3.6.7.3.3.3 and 3.6.7.3.4.

Note 3.— Faults that occur in ground receivers used to generate the broadcast corrections are excluded from this requirement if they occur in any one, and only one, ground receiver at any time. Such faults are constrained by the requirement in 3.6.7.1.2.2.1.2 and the associated integrity risk requirement in 3.6.7.1.2.2.1 and 3.6.7.1.2.2.1.1.

3.6.7.1.2.1.2. Ground subsystem time to alert for GBAS approach services

3.6.7.1.2.1.2.1 Maximum time to alert for approach services

3.6.7.1.2.1.2.1.1 For a ground segment classified as FAST A, B, C or D the GBAS ground subsystem maximum time-to-alert shall be less than or equal to 3 seconds for all signal-in-space integrity requirements (see Appendix B, 3.6.7.1.2.1.1.1, 3.6.7.1.2.1.1.2, 3.6.7.1.2.2.1) when Type 1 messages are broadcast.

Note1 - The ground subsystem time-to-alert above is the time between the onset of the out-of-tolerance lateral or vertical relative position error and the transmission of the last bit of the message that contains the integrity data that reflects the condition (see Attachment D, 7.5.12.3).

Note 2.— For FAST D ground subsystems, additional range domain monitoring requirements apply as defined in section 3.6.7.3.3.2, 3.6.7.3.3.3 and 3.6.7.3.4. In these sections, time limits are defined for the ground system to detect and alert the airborne receiver of out-of-tolerance differential pseudo-range errors.

3.6.7.1.2.1.2.1.2 For a ground segment classified as FAST A, the GBAS ground subsystem maximum signal in space time-to-alert shall be less than or equal to 5.5 seconds when Type 101 messages are broadcast.

3.6.7.1.2.1.3 Ground subsystem FASLAL and FASVAL

3.6.7.1.2.1.3.1 For Message Type 4 FAS data blocks with APD coded as 1, 2, 3 or 4, the value FASLAL for each FAS block, as defined in the FAS lateral alert limit field of the Type 4 message shall be no greater than 40 meters, and the value FASVAL for each FAS block, as defined in the FAS vertical alert limit field of the Type 4 message, shall be no greater than 10 meters.

3.6.7.1.2.1.3.2.4 For Message Type 4 FAS data blocks with APD coded as zero, the value FASLAL and FASVAL shall be no greater than the lateral and vertical alert limits given in BCAR 10, Volume I, 3.7.2.4 for the intended operational use.

3.6.7.1.2.1.4 *Ground subsystem signal-in-space integrity risk for GBAS positioning service.* For GBAS ground subsystem that provides the GBAS positioning service, integrity risk shall be less than 9.9×10^{-8} per hour.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 239

Note 1 - The integrity risk assigned to the GBAS ground subsystem is a subset of the GBAS signal-in-space integrity risk, where the protection level integrity risk (3.6.7.1.2.2.2) has been excluded and the effects of all other GBAS, SBAS and core satellite constellations failures are included. The GBAS ground subsystem integrity risk includes the integrity risk of satellite signal monitoring required in .6.7.3.3.

Note 2 - GBAS signal-in-space integrity risk is defined as the probability that the ground subsystem provides information which when processed by a fault-free receiver, using any GBAS data that could be used by the aircraft, results in an out-of-tolerance horizontal relative position error without annunciation for a period longer than the maximum time-to-alert. An out-of-tolerance horizontal relative position error is defined as an error that exceeds both the horizontal protection level and the horizontal ephemeris error position bound.

3.6.7.1.2.1.4.1 *Time to alert for GBAS positioning service.* The GBAS ground subsystem maximum time-to-alert shall be less than or equal to 3 seconds when Type 1 messages are broadcast and less than or equal to 5.5 seconds when Type 101 messages are broadcast.

Note - The time-to-alert above is the time between the onset of the out-of-tolerance horizontal relative position error and the transmission of the last bit of the message that contains the integrity data that reflects the condition.

3.6.7.1.2.2 Protection level integrity risk

3.6.7.1.2.2.1 For a GBAS ground subsystem that provides GBAS approach services, the protection level integrity risk shall be less than 5×10^{-8} per approach.

Note -For approach services, the protection level integrity risk is the integrity risk due to undetected errors in the 100-second smoothed position solution relative to the GBAS reference point greater than the associated protection levels under the two following conditions:

- a) normal measurement conditions defined in 3.6.5.5.1.1 with D_v and D_L set to zero; and*
- b) faulted measurement conditions defined in 3.6.5.5.1.2 with D_v and D_L set to zero.*

Note.— The ground subsystem bounding of the 100-second smoothed GAST D position solution will ensure that the 30s smoothed GAST D position solution is bounded

3.6.7.1.2.2.1.1 *Additional bounding requirements for FAST D ground subsystems.* The σ_{vert} (used in computing the protection level VPL_{H0}) and σ_{lat} (used in computing the protection level LPL_{H0}) for GAST D formed, based on the broadcast parameters (defined in 3.6.5.5.1.1.1) and excluding the airborne contribution, shall satisfy the condition that a normal distribution with zero mean and a standard deviation equal to σ_{vert} and σ_{lat} bounds the vertical and lateral error distributions of the combined differential correction errors as follows:

$$\int_y^{\infty} f_n(x) dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \frac{y}{\sigma} \geq 0 \text{ and}$$

$$\int_{-\infty}^{-y} f_n(x) dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \frac{y}{\sigma} \geq 0$$

where

$f_n(x)$ = probability density function of the differential vertical or lateral position error excluding the airborne contribution, and

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} e^{-\frac{t^2}{2}} dt$$

The $\sigma_{\text{vert,H1}}$ (used in computing the protection level VPL_{H1}) and $\sigma_{\text{lat,H1}}$ (used in computing the protection level LPL_{H1}) for GAST D formed, based on the broadcast parameters (defined in 3.6.5.5.1.2) and excluding the airborne contribution, shall bound the combined differential correction errors (as defined above) formed by all possible subsets with one reference receiver excluded.

Note 1.— The airborne contribution is addressed in 3.6.8.3.2.1 in combination with the use of the standard airborne multipath model defined in 3.6.5.5.1.1.2.

Note 2.— The combined differential correction errors refer to code carrier smoothed corrections based on 100-second smoothing time constant.

3.6.7.1.2.2.2 For a GBAS ground subsystem that provides the positioning service, protection level integrity risk shall be less than 10^{-9} per hour.

Note - The GBAS positioning service protection level integrity risk is the integrity risk due to undetected errors in the horizontal position relative to the GBAS reference point greater than the GBAS positioning service protection level under the two following conditions:

- a) normal measurement conditions defined in 3.6.5.5.2.1; and
- b) faulted measurement conditions defined in 3.6.5.5.2.2.

3.6.7.1.3 Continuity of service

3.6.7.1.3.1 Continuity of service for *approach services*. The GBAS ground subsystem continuity of service shall be greater than or equal to $1 - 8.0 \times 10^{-6}$ per 15 seconds.

Note - The GBAS ground subsystem continuity of service is the average probability per 15-second period that the VHF data broadcast transmits data in tolerance, VHF data broadcast field strength is within the specified range and the protection levels are lower than the alert limits, including configuration changes that occur due to the space segment. This continuity of service requirement is the entire allocation of the signal-in-space continuity requirement from Chapter 3, Table 3.7.2.4-1, and therefore all continuity risks included in that requirement must be accounted for by the ground subsystem provider.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 241

3.6.7.1.3.2 *Additional continuity of service requirements for FAST D.* The probability of a GBAS ground subsystem failure or false alert, excluding ranging source monitoring, causing an unscheduled interruption of service for a period equal to or greater than 1.5 seconds shall not exceed 2.0×10^{-6} during any 15 second interval. The probability that the ground subsystem excludes any individual fault-free ranging source from the Type 1 or Type 11 corrections due to a false detection by the ground integrity monitors shall not exceed 2.0×10^{-7} during any 15 second interval.

Note 1.— Loss of service includes failures resulting in loss of the VHF data broadcast, failure to meet the VHF data broadcast field strength, failures resulting in transmission of out-of-tolerance VHF broadcast data, and alert due to an integrity failure. Guidance material on the potential causes of loss of service and monitor false detections are contained in Attachment D, 7.6.2.1.

Note 2. – Continuity for FAST D is defined as the probability that the ground subsystem continues to provide the services associated with the intended ground subsystem functions. Total aircraft continuity of navigation system performance in the position domain must be evaluated in the context of a specific satellite geometry and aeroplane integration. Evaluation of position domain navigation service continuity is the responsibility of the airborne user for GAST D. Additional information regarding continuity is given in Attachment D, 7.6.2.1.

3.6.7.1.3.3 Continuity of service for positioning service

Note - For GBAS ground subsystems that provide the GBAS positioning service, there may be additional continuity requirements depending on the intended operations.

3.6.7.2 Functional Requirements

3.6.7.2.1 General

3.6.7.2.1.1 Data broadcast requirements

3.6.7.2.1.1.1 A GBAS ground subsystem shall broadcast Messages types as defined in Table B-75A according to the service types supported by the ground subsystem.

3.6.7.2.1.1.2 Each GBAS ground subsystem shall broadcast Type 2 messages with additional data blocks as required to support the intended operations.

Note.— Guidance material concerning usage of the Type 2 message additional data blocks is provided in Attachment D, 7.17.

3.6.7.2.1.1.3 Each GBAS ground subsystem which supports GBAS approach service type (GAST) B, C or D shall broadcast FAS blocks in Type 4 messages for these approaches. If a GBAS ground subsystem supports any approach using GAST A or B and does not broadcast FAS blocks for the corresponding approaches, it shall broadcast additional data block 1 in the Type 2 message.

Note.— FAS blocks for APV procedures may be held within a database on board the aircraft. Broadcasting additional data block 1 allows the airborne receiver to select the GBAS ground subsystem that supports the approach procedures in the airborne database. FAS blocks may also be broadcast to support operations by aircraft without an airborne database. These procedures use different channel numbers as described in Attachment D, 7.7.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

3.6.7.2.1.1.4 When the Type 5 message is used, the ground subsystem shall broadcast the Type 5 message at a rate in accordance with Table B-76.

Note.— When the standard 5 degree mask is not adequate to describe satellite visibility at either the ground subsystem antennas or at an aircraft during a specific approach, the Type 5 message may be used to broadcast additional information to the aircraft.

3.6.7.2.1.1.5 Data broadcast rates. For all message types required to be broadcast, messages meeting the field strength requirements of Chapter 3, 3.7.3.5.4.4.1.2 and 3.7.3.5.4.4.2.2 and the minimum rates shown in Table B-76 shall be provided at every point within the service volume. The total message broadcast rates from all antenna systems of the ground subsystem combined shall not exceed the maximum rates shown in Table B-76.

Note.— Guidance material concerning the use of multiple antenna systems is provided in Attachment D, 7.12.4.

3.6.7.2.1.2 Message block identifier. The MBI shall be set to either normal or test according to the coding given in 3.6.3.4.1

Table B-147. GBAS message types for supported service types

<i>Message type</i>	<i>GAST A – Note 1</i>	<i>GAST B – Note 1</i>	<i>GAST C – Note 1</i>	<i>GAST D – Note 1</i>
MT 1	Optional – Note 2	Required	Required	Required
MT 2	Required	Required	Required	Required
MT2-ADB 1	Optional – Note 3	Optional – Note 3	Optional – Note 3	Required
MT2-ADB 2	Optional – Note 4	Optional – Note 4	Optional – Note 4	Optional
MT2-ADB 3	Not used	Not used	Not used	Required
MT2-ADB 4	Recommended	Recommended	Recommended	Required
MT3-Note 5	Recommended	Recommended	Recommended	Required
MT 4	Optional	Required	Required	Required
MT 5	Optional	Optional	Optional	Optional
MT11 – Note 6	Not used	Not used	Not used	Required
MT 101	Optional – Note 2	Not allowed	Not allowed	Not allowed

Note 1.— Definition of terms:

- *Required: Message needs to be transmitted when supporting the service type;*
- *Optional: Message transmission is optional when supporting the service type (not used by some or all airborne subsystems);*
- *Recommended: Use of the message is optional, but recommended, when supporting the service type;*
- *Not used: Message is not used by airborne subsystems for this service type;*
- *Not allowed: Message transmission is not allowed when supporting the service type.*

Note 2.— Ground subsystems supporting GAST A service types may broadcast Type 1 or 101 Messages, but not both. Guidance material concerning usage of the Type 101 message is provided in Attachment D, 7.18.

Note 3.— MT2-ADB1 is required if positioning service is offered.

Note 4.— MT2-ADB2 is required if GRAS service is offered.

Note 5.— MT3 is recommended (GAST A, B, C) or required (GAST-D) to be used only in order to meet slot occupancy requirements in 3.6.7.4.1.3.

Note 6.— Guidance material concerning usage of the Type 11 message is provided in Attachment D, 7.20.

Table B-148. GBAS VHF data broadcast rates

<i>Message type</i>	<i>Minimum broadcast rate</i>	<i>Maximum broadcast rate</i>
1 or 101	For each measurement type: All measurement blocks once per frame (Note)	For each measurement type: All measurement blocks once per slot
2	Once per 20 consecutive frames	Once per frame (except as stated in 3.6.7.4.1.2)
3	Rate depends on message length and scheduling of other messages (see 3.6.7.4.1.3)	Once per slot and eight times per frame
4	All FAS blocks once per 20 consecutive frames	All FAS blocks once per frame
5	All impacted sources once per 20 consecutive frames	All impacted sources once per 5 consecutive frames
11	For each measurement type: All measurement blocks once per frame (see Note)	For each measurement type: All measurement blocks once per slot

Note.— One Type 1, Type 11 or Type 101 message or two Type 1, Type 11 or Type 101 messages that are linked using the additional message flag described in 3.6.4.2, 3.6.4.10.3 or 3.6.4.11.3.

3.6.7.2.1.3 VDB authentication

3.6.7.2.1.3.1 All GBAS ground subsystems should support VDB authentication (section 3.6.7.4).

3.6.7.2.1.3.2 All ground subsystems classified as FAST D shall support VDB authentication (section 3.6.7.4).

3.6.7.2.2 Pseudo-range corrections

3.6.7.2.2.1 Message latency. The time between the time indicated by the modified Z-count and the last bit of the broadcast Type 1, Type 11 or Type 101 message shall not exceed 0.5 seconds.

3.6.7.2.2.2 Low-frequency data: Except during an ephemeris change, the first ranging source in the Type 1, Type 11 or Type 101 message shall sequence so that the ephemeris decorrelation parameter, ephemeris CRC and source availability duration for each core satellite constellation's ranging source are transmitted at least once every 10 seconds. During an ephemeris change, the first ranging source shall sequence so that the ephemeris decorrelation parameter, ephemeris CRC and source availability duration for each core satellite constellation's ranging source are transmitted at least once every 27 seconds. When new ephemeris data are received from a core satellite constellation's ranging source, the ground subsystem shall use the previous ephemeris data from each satellite until the new ephemeris data have been continuously received for at least 2 minutes but shall make a transition to the new ephemeris data before 3 minutes have passed. When this transition is made to using the new ephemeris data for a given ranging source, the ground subsystem shall broadcast the new ephemeris CRC and associated low frequency information, notably P and P_D for all occurrences of that ranging source in the low-frequency information of Type 1 or Type 101 message in the next 3 consecutive frames. For a given ranging source, the ground subsystem shall continue to transmit data corresponding to the previous ephemeris data until the new CRC ephemeris is transmitted in the low-frequency data of Type 1, Type 11 or Type 101 message (see Note). If the ephemeris CRC changes and the IOD does not, the ground subsystem shall consider the ranging source invalid.

Note.— The delay before the ephemeris transition allow sufficient time for the aircraft subsystem to collect new ephemeris data.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 244

3.6.7.2.2.2.1 The ephemeris decorrelation parameter and the ephemeris CRC for each core satellite constellation's ranging source should be broadcast as frequently as possible.

3.6.7.2.2.3 Broadcast pseudo-range correction. Each broadcast pseudo-range correction shall be determined by combining the pseudo-range correction estimates for the relevant ranging source calculated from each of the reference receivers. For each satellite, the measurements used in this combination shall be obtained from the same ephemeris data. The corrections shall be based on smoothed code pseudo-range measurements for each satellite using the carrier measurement from a smoothing filter and the approach service type specific smoothing parameters in accordance with Appendix B, section 3.6.5.1.

3.6.7.2.2.4 Broadcast signal-in-space integrity parameters. The ground subsystem shall provide σ_{pr_gnd} and B parameters for each pseudo-range correction in Type 1 message such that the protection level integrity risk requirements defined in 3.6.7.1.2.2 for GAST A, B and C are satisfied. At least two B values that are not using the special coding (as defined in section 3.6.4.2.4) shall be provided with each pseudo-range correction. The ground subsystem shall provide σ_{pr_gnd} and, if necessary, B parameters for each pseudo-range correction in Type 101 message such that the protection level integrity risk requirements defined in 3.6.7.1.2.2 are satisfied.

Note.— Broadcast of the B parameters are optional for Type 101 messages. Guidance material regarding the B parameters in Type 101 messages is contained in Attachment D, 7.5.11.

3.6.7.2.2.4.1 *Broadcast signal-in-space integrity parameters for FAST D Ground subsystems.* Ground subsystems that support GAST D shall provide Sigma_PR_gnd_D in the Type 11 message and B parameters for each pseudo-range correction in the Type 1 message such that the protection level integrity risk requirement defined in 3.6.7.1.2.2.1 is satisfied.

3.6.7.2.2.4.2 For FAST D systems broadcasting the Type 11 message, if σ_{pr_gnd} is coded as invalid in the Type 1 message, then the Sigma_PR_gnd_D for the associated satellite in the Type 11 message shall also be coded as invalid.

3.6.7.2.2.5 Reference receiver measurements should be monitored. Faulted measurements or failed reference receivers should not be used to compute the pseudo-range corrections.

3.6.7.2.2.6 Repeated transmission of Type 1, Type 2, Type 11 or Type 101 messages. For a given measurement type and within a given frame, all broadcasts of Type 1 Type 2, Type 11 or Type 101 messages or linked pairs from all GBAS broadcast stations that share a common GBAS identification, shall have identical data content.

3.6.7.2.2.7 Issue of data. The GBAS ground subsystem shall set the IOD field in each ranging source measurement block to be the IOD value received from the ranging source that corresponds to the ephemeris data used to compute the pseudo-range correction.

3.6.7.2.2.8 Application of signal error models. Ionospheric and tropospheric corrections shall not be applied to the pseudo-ranges used to calculate the pseudo-range corrections.

3.6.7.2.2.9 Linked pair of Type 1, Type 11 or Type 101 messages. If a linked pair of Type 1, Type 11 or Type 101 messages is transmitted then,

- a) the two messages shall have the same modified Z-count;
- b) the minimum number of pseudo-range corrections in each message shall be one;

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 245

- c) the measurement block for a given satellite shall not be broadcast more than once in a linked pair of messages;
- d) the two messages shall be broadcast in different time slots;
- e) the order of the B values in the two messages shall be the same;
- f) for a particular measurement type, the number of measurements and low-frequency data shall be computed separately for each of the two individual messages;
- g) in the case of FAST D, when a pair of linked Type 1 messages are transmitted, there shall also be a linked pair of Type 11 messages; and
- h) if linked message types of Type 1 or Type 11 are used, the satellites shall be divided into the same sets and order in both Type 1 and Type 11 messages.

Note. — Type 1 messages may include additional satellites not available in Type 11 messages, but the relative order of those satellites available in both messages is the same in Type 1 and Type 11 messages. Airborne processing is not possible for satellites included in the Type 11 message but not included in the associated Type 1 message.

3.6.7.2.2.9.1 Linked messages should only be used when there are more pseudo-range corrections to transmit than will fit in one Type 1 message.

3.6.7.2.2.10 Modified Z-count requirements

3.6.7.2.2.10.1 Modified Z-count update. The modified Z-count for Type 1 or Type 101 messages of a given measurement type shall advance every frame.

3.6.7.2.2.10.2 If Message Type 11 is broadcast, the associated Type 1 and Type 11 messages shall have the same modified Z-count.

3.6.7.2.2.11 Ephemeris de correlation parameters

3.6.7.2.2.11.1 Ephemeris decorrelation parameter for approach services. For ground subsystems that broadcast the additional data block 1 in the Type 2 message, the ground subsystem shall broadcast the ephemeris decorrelation parameter in type 1 message for each core satellite constellation ranging source such that the ground subsystem integrity risk of 3.6.7.1.2.1.1.1 is met.

3.6.7.2.2.11.2 Ephemeris decorrelation parameter for GAST D. Ground subsystems classified as FAST D shall broadcast the ephemeris decorrelation parameter in the Type 11 message for each core satellite constellation ranging source such that the ground subsystem signal-in-space integrity risk of 3.6.7.1.2.1.1.3 is met.

3.6.7.2.2.11.3 GBAS positioning service. For ground subsystems that provide the GBAS positioning service, the ground subsystem shall broadcast the ephemeris decorrelation in the type 1 message parameter for each core satellite constellation's ranging source such that the ground subsystem signal in space integrity risk of 3.6.7.1.2.1.4 is met.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 246

3.6.7.2.3 GBAS-related data

3.6.7.2.3.1 Tropospheric delay parameters. The ground subsystem shall broadcast a refractivity index, scale height, and refractivity uncertainty in a Type 2 message such that the protection level integrity risk requirements defined in 3.6.7.1.2.2 are satisfied.

3.6.7.2.3.2 GCID indication.

3.6.7.2.3.2.1 *GCID indication for FAST A, B or C.* If the ground subsystem meets the requirements of 3.6.7.1.2.1.1.1, 3.6.7.1.2.2.1, 3.6.7.1.3.1, 3.6.7.3.2 and 3.6.7.3.3.1 but not all of 3.6.7.1.2.1.1.2, 3.6.7.1.2.1.1.3, 3.6.7.1.2.2.1.1, and 3.6.7.1.3.2 the GCID shall be set to 1, otherwise it shall be set to 7.

Note.— Some of the requirements applicable to FAST D are redundant with the FAST A, B and C requirements. The phrase “not all of” refers to the condition where a ground subsystem may meet some of the requirements applicable to FAST D but not all of them. Therefore, in that condition the GCID would be set to 1, indicating that the ground subsystem meets only FAST A, B or C.

3.6.7.2.3.2.2 *GCID indication for FAST D.* If the ground subsystem meets the requirements of 3.6.7.1.2.1.1.1, 3.6.7.1.2.1.1.2, 3.6.7.1.2.1.1.3, 3.6.7.1.2.2.1.1, 3.6.7.1.2.2.1, 3.6.7.1.3.1, 3.6.7.1.3.2, 3.6.7.3.2 and 3.6.7.3.3, the GCID shall be set to 2, otherwise it shall be set in accordance with 3.6.7.2.3.2.1.

3.6.7.2.3.2.3 GCID values of 3 and 4 are reserved for future service types and shall not be used.

3.6.7.2.3.3 GBAS reference antenna phase center position accuracy. For each GBAS reference receiver, the reference antenna phase center position error shall be less than 8 cm relative to the GBAS reference point.

3.6.7.2.3.4 GBAS reference point survey accuracy. The survey error of the GBAS reference point, relative to WGS-84, should be less than 0.25 m vertical and 1 m horizontal.

Note - Relevant guidance material is given in Attachment D, 7.16.

3.6.7.2.3.5 Ionospheric uncertainty estimate parameter.

3.6.7.2.3.5.1 Ionospheric uncertainty estimate parameter for all ground subsystems. The ground subsystem shall broadcast an ionospheric delay gradient parameter in the Type 2 message such that the protection level integrity risk requirements defined in 3.6.7.1.2.2 are satisfied.

3.6.7.2.3.5.2 *Ionospheric uncertainty estimate parameter for FAST D ground subsystems.* The ground subsystem shall broadcast an ionospheric delay gradient parameter in the Type 2 message, additional data block 3, such that the protection level integrity risk requirements defined in 3.6.7.1.2.2 are satisfied.

Note.— Guidance material concerning FAST D position domain error bounding for ionospheric errors may be found in Attachment D, 7.5.6.1.3 and 7.5.6.1.4.

3.6.7.2.3.6 For ground subsystems that provide the GBAS positioning service, the ground subsystem shall broadcast the ephemeris error position bound parameters using additional data block 1 in the Type 2 message.

3.6.7.2.3.7 All ground subsystems should broadcast the ephemeris error position bound parameters using additional data block 1 in the Type 2 message.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 247

3.6.7.2.3.8 For ground subsystems that broadcast additional data block 1 in the Type 2 message, the following requirements shall apply:

3.6.7.2.3.8.1 Maximum use distance. The ground subsystem shall provide the maximum use distance (D_{max}). When the positioning service is provided the ground subsystem integrity risk in 3.6.7.1.2.1.4 and the protection level integrity risk in 3.6.7.1.2.2.2 shall be met within D_{max} . When approach service is provided, the maximum use distance shall at least encompass all approach service volumes supported.

3.6.7.2.3.8.2 Ephemeris missed detection parameters. The ground subsystem shall broadcast the ephemeris missed detection parameters for each core satellite constellation such that the ground subsystem integrity risk of 3.6.7.1.2.1 is met.

3.6.7.2.3.8.3 GBAS positioning service indication. If the ground subsystem does not meet the requirements of 3.6.7.1.2.1.2 and 3.6.7.1.2.2.2, the ground subsystem shall indicate using the RSDS parameter that the GBAS positioning service is not provided.

3.6.7.2.3.9 If the VHF data broadcast is transmitted at more than one frequency within the GRAS service area, each GBAS broadcast station within the GRAS ground subsystem shall broadcast additional data blocks 1 and 2.

3.6.7.2.3.9.1 The VHF data broadcast should include additional data block 2 parameters to identify channel numbers and locations of adjacent and nearby GBAS broadcast stations within the GRAS ground subsystem.

Note - This facilitates the transition from one GBAS broadcast station to other GBAS broadcast stations in the GRAS ground subsystem.

3.6.7.2.4 Final approach segment data

3.6.7.2.4.1 FAS data points accuracy. The relative survey error between the FAS data points and the GBAS reference point shall be less than 0.25 meters vertical and 0.40 meters horizontal.

3.6.7.2.4.2 The final approach segment CRC should be assigned at the time of procedure design, and kept as an integral part of the FAS data block from that time onward.

3.6.7.2.4.3 The GBAS should allow the capability to set the FASVAL and FASLAL for any FAS data block to “1111 1111” to limit the approach to lateral only or to indicate that the approach must not be used, respectively.

3.6.7.2.4.4 *LTP/FTP for FAST D*. For an approach that supports GAST D, the LTP/FTP point in the corresponding FAS definition shall be located at the intersection of the runway centerline and the landing threshold.

Note. — Airborne systems may compute the distance to the landing threshold using the LTP/FTP. For GAST D approaches, the LTP/FTP is to be at the threshold so that these distance to go computations reliably reflect the distance to the threshold.

3.6.7.2.4.5 *FPAP location for FAST D*. For an approach that supports GAST D, the FPAP point in the corresponding FAS definition shall be located on the extended runway centerline and the Δ Length offset parameter shall be coded to correctly indicate the stop end of the runway.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 248

3.6.7.2.5 Predicted ranging source availability data

Note - Ranging source availability data are optional for FAST A, B, C or D ground subsystems and may be required for possible future operations.

3.6.7.2.6 General functional requirements on augmentation

3.6.7.2.6.1 GBAS ground subsystems classified as FAST C or FAST D should provide augmentation based on GPS at a minimum.

3.6.7.2.6.2 Ground subsystems classified as FAST C should be able to process and broadcast corrections for at least 12 satellites of each core constellation for which differential corrections are provided.

3.6.7.2.6.3 Ground subsystems classified as FAST D shall be able to process and broadcast differential corrections for at least 12 satellites of one core constellation.

Note.— Technical validation has only been completed for GAST D when applied to GPS.

3.6.7.2.6.4 Whenever possible, differential corrections for all visible satellites with an elevation greater than 5 degrees above the local horizontal plane tangent to the ellipsoid at the ground subsystem reference location should be provided for each core constellation for which augmentation is provided.

Note.— The phrase “whenever possible” in this context means whenever meeting another requirement in these SARPs (for example 3.6.7.3.3.1) does not preclude providing a differential correction for a particular satellite.

3.6.7.3 Monitoring

3.6.7.3.1 RF monitoring

3.6.7.3.1.1 VHF data broadcast monitoring. The data broadcast transmissions shall be monitored. The transmission of the data shall cease within 0.5 seconds in case of continuous disagreement during any 3-second period between the transmitted application data and the application data derived or stored by the monitoring system prior to transmission. For FAST D ground subsystems, the transmission of the data shall cease within 0.5 seconds in case of continuous disagreement during any 1-second period between the transmitted application data and the application data derived or stored by the monitoring system prior to transmission.

Note.— For ground subsystems that support authentication, ceasing the transmission of data means ceasing the transmission of Type 1 messages and Type 11 messages if applicable or ceasing the transmission of Type 101 messages. In accordance with 3.6.7.4.1.3, the ground subsystem must still transmit messages such that the defined percentage or more of every assigned slot is occupied. This can be accomplished by transmitting Type 2, Type 3, Type 4 and/or Type 5 messages.

3.6.7.3.1.2 TDMA slot monitoring. The risk that the ground subsystem transmits a signal in an unassigned slot and fails to detect an out-of-slot transmission, which exceeds that allowed in 3.6.2.6, within 1 second, shall be less than 1×10^{-7} in any 30-second period. If out-of-slot transmissions are detected, the ground subsystem shall terminate all data broadcast transmissions within 0.5 seconds.

3.6.7.3.1.3 VDB transmitter power monitor. The probability that the horizontally or elliptically polarized signal's transmitted power increases by more than 3 dB from the nominal power for more than 1 second shall be less than 2.0×10^{-7} in any 30-second period.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 249

Note - The vertical component is only monitored for GBAS/E equipment.

3.6.7.3.2 Data monitoring

3.6.7.3.2.1 Broadcast quality monitor. The ground subsystem monitoring shall comply with the time-to-alert requirements given in 3.6.7.1.2.1. The monitoring action shall be one of the following:

- a) to broadcast Type 1 (and Type 11 if broadcast) or Type 101 messages with no measurement blocks; or
- b) to broadcast Type 1 (and Type 11 if broadcast) or Type 101 messages with the $\sigma_{pr_gnd,i}$ (and $\sigma_{pr_gnd,D,I}$ if broadcast) field set to indicate the ranging source is invalid for every ranging source included in the previously transmitted frame; or
- c) to terminate the data broadcast.

Note - Monitoring actions a) and b) are preferred to c) if the particular failure mode permits such a response, because actions a) and b) typically have a reduced signal-in-space time-to-alert.

3.6.7.3.3 Integrity monitoring for GNSS ranging sources

3.6.7.3.3.1 The ground subsystem shall monitor the satellite signals to detect conditions that will result in improper operation of differential processing for airborne receivers complying with the tracking constraints in Attachment D, 8.11. The monitor time-to-alert shall comply with 3.6.7.1.2. The monitor action shall be to set σ_{pr_gnd} to the bit pattern “1111 1111” for the satellite or to exclude the satellite from the Type 1, Type 11 or Type 101 message.

3.6.7.3.3.1.1 The ground subsystem shall use the strongest correlation peak in all receivers used to generate the pseudo-range corrections. The ground subsystem shall also detect conditions that cause more than one zero crossing for airborne receivers that use the Early-Late discriminator function as described in Attachment D, 8.11.

3.6.7.3.3.2 For FAST D ground subsystems, the probability that the error at the landing threshold point (LTP) of any runway for which the ground subsystem supports GAST D, |Er|, on the 30-second smoothed corrected pseudo-range (section 3.6.5.2) caused by a ranging source fault, is not detected and reflected in the broadcast Type 11 message within 1.5 s shall fall within the region specified in Table B-76 A.

Ranging source faults for which this requirement applies are:

- a) signal deformation (Note 1.);
- b) code/carrier divergence;
- c) excessive pseudo-range acceleration, such as a step or other rapid change; and
- d) erroneous broadcast of ephemeris data from the satellite.

Note 1.— Refer to Appendix D, section 8.11 for further information on GAEC-D avionics relating to signal deformation fault.

Note 2.— Upon detection, a ranging source fault may be reflected in the Type 11 message by either:

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

- a) removing the correction for the associated satellite from the Type 11 message; or
- b) marking the satellite as invalid using the coding of $\sigma_{pr_gnd_D}$ (section 3.6.4.11.4).

Note 3.— The acceptable probability of missed detection region is defined with respect to differentially corrected pseudo-range error. The differentially corrected pseudo-range error, $|Er|$, includes the error resulting from a single ranging source fault, given the correct application of GBAS ground subsystem Message Type 11 broadcast corrections (i.e. pseudo-range correction and range rate corrections defined in Section 3.6.4.11) by the aircraft avionics as specified within section 3.6.8.3. Evaluation of P_{md} performance includes GBAS ground subsystem fault-free noise. The growth of $|Er|$ with time should consider the data latency of the ground subsystem, but not the airborne latency, as described in section 7.5.12.3.

Note 4.— Additional information regarding the ranging source fault conditions and monitoring requirements for FAST D ground subsystems may be found in Attachment D, 7.5.12. Missed messages do not need to be considered as part of compliance with this requirement.

Table B-149. P_{md_limit} parameters

Probability of Missed Detection	Pseudo-range Error (metres)
$P_{md_limit} \leq 1$	$0 \leq Er < 0.75$
$P_{md_limit} \leq 10^{(-2.56 \times Er + 1.92)}$	$0.75 \leq Er < 2.7$
$P_{md_limit} \leq 10^{-5}$	$2.7 \leq Er < \infty$

3.6.7.3.3.3 For FAST D ground subsystems, the probability that an error at the landing threshold point (LTP) of any runway for which the ground subsystem supports GAST D, $|Er|$, greater than 1.6 metres on the 30-second smoothed corrected pseudo-range (section 3.6.5.2), caused by a ranging source fault, is not detected and reflected in the broadcast Type 11 message within 1.5 seconds shall be less than 1×10^{-9} in any one landing when multiplied by the prior probability (*Papriori*).

Ranging source faults for which this requirement applies are:

- a) signal deformation (Note 1.);
- b) code/carrier divergence;
- c) excessive pseudo-range acceleration, such as a step or other rapid change; and
- d) erroneous broadcast of ephemeris data from the satellite.

Note 1.— Refer to Appendix D, 8.11 for further information on GAEC-D avionics relating to signal deformation fault.

Note 2.— It is intended that the prior probability of each ranging source fault (*Papriori*) be the same value that is used in the analysis to show compliance with error bounding requirements for FAST C and D (see Appendix B, 3.6.5.5.1.1.1).

Note 3.— Upon detection, a ranging source fault may be reflected in the Type 11 message by either:

- a) removing the faulty satellite correction from the Type 11 message; or

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 251

b) marking the satellite as invalid using the coding of $\sigma_{pr_gnd_D}$ (section 3.6.4.11.4).

Note 4.— Additional information regarding the ranging source fault conditions and monitoring requirements for FAST D ground subsystems may be found in Attachment D, 7.5.12. Missed messages do not need to be considered as part of compliance with this requirement.

3.6.7.3.4 Ionospheric gradient mitigation

For FAST D ground subsystems, the probability of an error ($|Er|$) in the 30-second smoothed corrected pseudo-range at the landing threshold point (LTP) for every GAST D supported runway that (a) is caused by a spatial ionospheric delay gradient, (b) is greater than the EIG value computed from broadcast Type 2 message, and (c) is not detected and reflected in the broadcast Type 11 message within 1.5 seconds shall be less than 1×10^{-9} in any one landing. The FAST D ground subsystem shall limit the Type 2 broadcast parameters to ensure that the maximum EIG at every LTP supporting GAST D operations shall not exceed 2.75 metres except when operational requirements are demonstrated to permit it.

Note 1.— The total probability of an undetected delay gradient includes the prior probability of the gradient and the monitor(s) probability of missed detection.

Note 2.— Validation guidance for ionospheric gradient mitigation can be found in 7.5.6.1.8.

Note 3.— To broadcast Type 2 parameters such that EIG exceeds 2.75 m for a specific LTP supporting GAST D operations, a tailored analysis will demonstrate that the resulting GAST D continuity and availability supports the intended operation. Guidance for assessing acceptability of EIG exceeding 2.75 m can be found in 7.5.13.1.

3.6.7.4 Functional requirements for authentication protocols

3.6.7.4.1 Functional requirements for ground subsystems that support authentication

3.6.7.4.1.1 The ground system shall broadcast the additional data block 4 with the Type 2 message with the slot group definition field coded to indicate which slots are assigned to the ground station.

3.6.7.4.1.2 The ground subsystem shall broadcast every Type 2 message only in one of a set of slots defined as the MT 2 sanctioned slots. The first slot in the group of MT 2 sanctioned slots corresponds to the SSID coding for the ground subsystem. Slot A is represented by SSID = 0, B by 1, C by 2, and H by 7. The group of MT 2 sanctioned slots then also includes the next slot after the slot corresponding to the station SSID if it exists in the frame. If there is not an additional slot before the end of the frame, only the SSID is included in the set.

Note.— For example, the MT 2 sanctioned slot group for SSID = 0 would include slots {A, B} while the MT 2 sanctioned slot group for SSID = 6 would include slots {G, H}. The MT 2 sanctioned slot group for SSID = 7 includes slot {H} only.

3.6.7.4.1.2.1 The set of slots assigned to a ground station shall include at a minimum all the slots in the MT 2 sanctioned slots as described in section 3.6.7.4.1.2.

3.6.7.4.1.3 Assigned slot occupancy. The ground subsystem shall transmit messages such that 89 per cent or more of every assigned slot is occupied. If necessary, Type 3 messages may be used to fill unused space in any assigned time slot.

Note 1.— More information on the calculation of the slot occupancy is provided in Attachment D, 7.21.

Note 2.— The requirement applies to the aggregate transmissions from all transmitters of a GBAS ground subsystem. Due to signal blockage, not all of those transmissions may be received in the service volume.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

3.6.7.4.1.4 Reference path identifier coding. Every reference path identifier included in every final approach segment data block broadcast by the ground subsystem via the Type 4 messages shall have the first letter selected to indicate the SSID of the ground subsystem in accordance with the following coding.

Coding: A = SSID of 0
X = SSID of 1
Z = SSID of 2
J = SSID of 3
C = SSID of 4
V = SSID of 5
P = SSID of 6
T = SSID of 7

3.6.7.4.2 Functional requirements for ground subsystems that do not support authentication

3.6.7.4.2.1 Reference path identifier coding. Characters in this set: {A X Z J C V P T} shall not be used as the first character of the reference path identifier included in any FAS block broadcast by the ground subsystem via the Type 4 messages.

3.6.8 Aircraft Elements

3.6.8.1 GNSS receiver. The GBAS-capable GNSS receiver shall process signals of GBAS in accordance with the requirements specified in this section as well as with requirements in 3.1.3.1 and/or 3.2.3.1 and/or 3.5.8.1.

Note. — In order to ensure the required performance and functional objectives for GAST D are achieved, it is necessary for the airborne equipment to meet defined performance and functional standards. The relevant minimum operational performance standards are detailed in RTCA DO-253D.

3.6.8.2 Performance Requirements

3.6.8.2.1 GBAS aircraft receiver accuracy

3.6.8.2.1.1 The RMS of the total aircraft receiver contribution to the error for GPS and GLONASS shall be:

$$\text{RMS}_{\text{pr_air}}(\theta_n) \leq a_0 + a_1 \times e^{-(\theta_n/\theta_0)}$$

where

n = the nth ranging source;
 θ_n = the elevation angle for the nth ranging source; and
 a_0 , a_1 , and θ_0 = as defined in Table B-150 for GPS and Table B-151 for GLONASS.

3.6.8.2.1.2 The RMS of the total aircraft receiver contribution to the error for SBAS satellites shall be as defined in 3.5.8.2.1 for each of the defined aircraft accuracy designators.

Note - The aircraft receiver contribution does not include the measurement error induced by airframe multipath.

Table B-150. Aircraft GPS receiver accuracy requirement

<i>Aircraft accuracy designator</i>	θ_n (degrees)	a_0 (metres)	a_1 (metres)	θ_0 (degrees)
A	≥ 5	0.15	0.43	6.9
B	≥ 5	0.11	0.13	4

Table B-151. Aircraft GLONASS receiver accuracy requirement

<i>Aircraft accuracy designator</i>	θ_n (degrees)	a_0 (metres)	a_1 (metres)	θ_0 (degrees)
A	≥ 5	0.39	0.9	5.7
B	≥ 5	0.105	0.25	5.5

3.6.8.2.2 VHF data broadcast receiver performance

3.6.8.2.2.1 VHF data broadcast tuning range. The VHF data broadcast receiver shall be capable of tuning frequencies in the range of 108.000 – 117.975 MHz in increments of 25 kHz.

3.6.8.2.2.2 VHF data broadcast capture range. The VHF data broadcast receiver shall be capable of acquiring and maintaining lock on signals within ± 418 Hz of the nominal assigned frequency.

Note - The frequency stability of the GBAS ground subsystem, and the worst-case doppler shift due to the motion of the aircraft, are reflected in the above requirement. The dynamic range of the automatic frequency control should also consider the frequency-stability error budget of the aircraft VHF data broadcast receiver.

3.6.8.2.2.3 VHF data broadcast message failure rate. The VHF data broadcast receiver shall achieve a message failure rate less than or equal to one failed message per 1 000 full-length (222 bytes) application data messages, within the range of the RF field strength defined in 3.7.3.5.4.4 as received by the airborne antenna, provided that the variation in the average received signal power between successive bursts in a given time slot does not exceed 40 dB. Failed messages include those lost by the VHF data broadcast receiver system or which do not pass the CRC after application of the FEC.

Note 1.— An aircraft VHF data broadcast receiving antenna can be horizontally or vertically polarized. Due to the difference in the signal strength of horizontally and vertically polarized components of the broadcast signal, the maximum total aircraft implementation loss for horizontally polarized receiving antennas is 4 dB higher than the maximum loss and vertically polarized receiving antennas. For guidance in determining aircraft implementation loss see Attachment D, 7.2.

Note 2.— It is acceptable to exceed the signal power variation requirement in limited parts of the service volume when operational requirements permit. Refer to Attachment D, 7.12.4.1 for guidance.

3.6.8.2.2.4 VHF data broadcast time slot decoding. The VHF data broadcast receiver shall meet the requirements of 3.6.8.2.2.3 for all message type required (section 3.6.8.3.1.2.1) from the selected GBAS ground subsystem. These requirements shall be met in the presence of other GBAS transmissions in any and all time slots respecting the levels as indicated in 3.6.8.2.2.5.1 b).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 254

Note.— Other GBAS transmissions may include: a) other message types with the same SSID, and b) messages with different SSIDs.

3.6.8.2.2.5 Co-channel rejection

3.6.8.2.2.5.1 VHF data broadcast as the undesired signal source. The VHF data broadcast receiver shall meet the requirements specified in 3.6.8.2.2.3 in the presence of an undesired co-channel VHF data broadcast signal that is either:

- a) assigned to the same time slot(s) and 26 dB below the desired VHF data broadcast signal power at the receiver input or lower; or
- b) assigned different time slot(s) and no more than 72 dB above the minimum desired VHF data broadcast signal field strength defined in 3.7.3.5.4.4.

3.6.8.2.2.5.2 VOR as the undesired signal. The VHF data broadcast receiver shall meet the requirements specified in 3.6.8.2.2.3 in the presence of an undesired co-channel VOR signal that is 26 dB below the desired VHF data broadcast signal power at the receiver input.

3.6.8.2.2.6 Adjacent channel rejection

3.6.8.2.2.6.1 First adjacent 25 kHz channels (± 25 kHz). The VHF data broadcast receiver shall meet the requirements specified in 3.6.8.2.2.3 in the presence of a transmitted undesired signal offset by 25 kHz on either side of the desired channel that is either:

- a) 18 dB above the desired signal power at the receiver input when the undesired signal is another VHF data broadcast signal assigned to the same time slot(s); or
- b) equal in power at the receiver input when the undesired signal is VOR.

3.6.8.2.2.6.2 Second adjacent 25 kHz channels (± 50 kHz). The VHF data broadcast receiver shall meet the requirements specified in 3.6.8.2.2.3 in the presence of a transmitted undesired signal offset by 50 kHz on either side of the desired channel that is either:

- a) 43 dB above the desired signal power at the receiver input when the undesired signal is another VHF data broadcast source assigned to the same time slot(s); or
- b) 34 dB above the desired signal power at the receiver input when the undesired signal is VOR.

3.6.8.2.2.6.3 Third and beyond adjacent 25 kHz channels (± 75 kHz or more). The VHF data broadcast receiver shall meet the requirements specified in 3.6.8.2.2.3 in the presence of a transmitted undesired signal offset by 75 kHz or more on either side of the desired channel that is either:

- a) 46 dB above the desired signal power at the receiver input when the undesired signal is another VHF data broadcast signal assigned to the same time slot(s); or
- b) 46 dB above the desired signal power at the receiver input when the undesired signal is VOR.

3.6.8.2.2.7 Rejection of off-channel signals from sources inside the 108.000 – 117.975 MHz band. With no on-channel VHF data broadcast signal present, the VHF data broadcast receiver shall not output data from an undesired VHF data broadcast signal on any other assignable channel.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

3.6.8.2.2.8 Rejection of signals from sources outside the 108.000 – 117.975 MHz band

3.6.8.2.2.8.1 VHF data broadcast interference immunity. The VHF data broadcast receiver shall meet the requirements specified in 3.6.8.2.2.3 in the presence of one or more signals having the frequency and total interference levels specified in Table B-79.

3.6.8.2.2.8.2 Desensitization. The VHF data broadcast receiver shall meet the requirements specified in 3.6.8.2.2.3 in the presence of VHF FM broadcast signals with signal levels shown in Tables B-80 and B-81.

Table B-152. Maximum levels of undesired signals

<i>Frequency</i>	<i>Maximum level of undesired signals at the receiver input (dB above S_{max})</i>
50 kHz up to 88 MHz	-12
88 MHz – 107.900 MHz	(see 3.6.8.2.2.8.2 and 3.6.8.2.2.8.3)
108.000 MHz – 117.975 MHz	Excluded
118.000 MHz	-43
118.025 MHz	-40
118.050 MHz up to 1 660.5 MHz	-12

Notes.—

- The relationship is linear between single adjacent points designated by the above frequencies.*
- These interference immunity requirements may not be adequate to ensure compatibility between VHF data broadcast receivers and VHF communication systems, particularly for aircraft that use the vertically polarized component of the VHF data broadcast. Without coordination between COM and NAV frequencies assignments or respect of a guard band at the top end of the 112 – 117.975 MHz band, the maximum levels quoted at the lowest COM VHF channels (118.000, 118.00833, 118.01666, 118.025, 118.03333, 118.04166, 118.05) may be exceeded at the input of the VDB receivers. In that case, some means to attenuate the COM signals at the input of the VDB receivers (e.g. antenna separation) will have to be implemented. The final compatibility will have to be assured when equipment is installed on the aircraft.*
- S_{max} is the maximum desired VHF data broadcast signal power at the receiver input.*

Table B-153. Desensitization frequency and power requirements that apply for VDB frequencies from 108.025 to 111.975 MHz

<i>Frequency</i>	<i>Maximum level of undesired signals at the receiver input (dB above S_{max})</i>
88 MHz $\leq f \leq$ 102 MHz	16
104 MHz	11
106 MHz	6
107.9 MHz	-9

Notes.—

- The relationship is linear between single adjacent points designated by the above frequencies.*
- This desensitization requirement is not applied for FM carriers above 107.7 MHz and VDB channels at 108.025 or 108.050 MHz. See Attachment D, 7.2.1.2.2.*
- S_{max} is the maximum desired VHF data broadcast signal power at the receiver input.*

3.6.8.2.2.8.3 VHF data broadcast FM intermodulation immunity. The VHF data broadcast receiver shall meet the requirements specified in 3.6.8.2.2.3 in the presence of interference from two-signal, third-order intermodulation products of two VHF FM broadcast signals having levels in accordance with the following:

Table B-154. Desensitization frequency and power requirements that apply for VDB frequencies from 112.000 to 117.975 MHz

<i>Frequency</i>	<i>Maximum level of undesired signals at the receiver input (dB above S_{max})</i>
88 MHz $\leq f \leq$ 104 MHz	16
106 MHz	11
107 MHz	6
107.9 MHz	1
<i>Notes.—</i>	
1. <i>The relationship is linear between single adjacent points designated by the above frequencies.</i>	
2. <i>S_{max} is the maximum desired VHF data broadcast signal power at the receiver input.</i>	

where the frequencies of the two VHF FM sound broadcasting signals produce, within the receiver, a two signal, third-order intermodulation product on the desired VDB frequency.

N_1 and N_2 are the levels (dBm) of the two VHF FM sound broadcasting signals at the VHF data broadcast receiver input.

Neither level shall exceed the desensitization criteria set forth in 3.6.8.2.2.8.2.

$f = 108.1 - f_1$, where f_1 is the frequency of N_1 , the VHF FM sound broadcasting signal closer to 108.1 MHz.

S_{max} is the maximum desired VHF data broadcast signal power at the receiver input.

Note - The FM intermodulation immunity requirements are not applied to a VHF data broadcast channel operating below 108.1 MHz, hence frequencies below 108.1 MHz are not intended for general assignments. Additional information is provided in Attachment D, 7.2.1.2.

3.6.8.3 Aircraft Functional Requirements

Note.— Unless otherwise specified, the following requirements apply to all GBAS airborne equipment classifications as described in Attachment D, 7.1.4.3.

3.6.8.3.1 Conditions for use of data

3.6.8.3.1.1 The receiver shall use data from a GBAS message only if the CRC of that message has been verified.

3.6.8.3.1.2 The receiver shall use message data only if the message block identifier is set to the bit pattern “1010 1010”.

3.6.8.3.1.2.1 GBAS message processing capability. The GBAS receiver shall at a minimum process GBAS message types in accordance with Table B-82.

Table B-155. Airborne equipment message type processing

<i>GBAS airborne equipment classification (GAEC)</i>	<i>Minimum message types processed</i>
GAEC A	MT 1 or 101, MT 2 (including ADB 1 and 2 if provided)
GAEC B	MT 1, MT 2 (including ADB 1 and 2 if provided), MT 4
GAEC C	MT 1, MT 2 (including ADB 1 if provided), MT 4
GAEC D	MT 1, MT 2 (including ADB 1, 2, 3 and 4), MT 4, MT 11

3.6.8.3.1.2.2 Airborne processing for forward compatibility

Note - Provisions have been made to enable future expansion of the GBAS Standards to support new capabilities. New message types may be defined, new additional data blocks for message Type 2 may be defined and new data blocks defining reference paths for inclusion within message Type 4 may be defined. To facilitate these future expansions, all equipment should be designed to properly ignore all data types that are not recognized.

3.6.8.3.1.2.2.1 Processing of unknown message types. The existence of messages unknown to the airborne receiver shall not prevent correct processing of the required messages.

3.6.8.3.1.2.2.2 Processing of unknown Type 2 extended data blocks. The existence of message Type 2 additional data blocks unknown to the airborne receiver shall not prevent correct processing of the required messages.

3.6.8.3.1.2.2.3 Processing of unknown Type 4 data blocks. The existence of message Type 4 data blocks unknown to the airborne receiver shall not prevent correct processing of the required messages.

Note -While the current SARPs include only one definition of a data block for inclusion within a Type 4 message, future GBAS Standards may include other reference path definitions.

3.6.8.3.1.3 The receiver shall use only ranging source measurement blocks with matching modified Z-counts.

3.6.8.3.1.4 If D_{max} is broadcast by the ground subsystem, the receiver shall only apply pseudo-range corrections when the distance to the GBAS reference point is less than D_{max} .

3.6.8.3.1.5 The receiver shall only apply pseudo-range corrections from the most recently received set of corrections for a given measurement type. If the number of measurement fields in the most recently received message types (as required in Appendix B, section 3.6.7.2.1.1.1 for the active service type) indicates that there are no measurement blocks, then the receiver shall not apply GBAS corrections for that measurement type.

3.6.8.3.1.6 Validity of pseudo-range corrections

3.6.8.3.1.6.1 When the active service type is A, B or C, the receiver shall exclude from the differential navigation solution any ranging sources for which σ_{pr_gnd} in the Type 1 or Type 101 messages is set to the bit pattern “1111 1111”.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 258

3.6.8.3.1.6.2 If the active service type is D, the receiver shall exclude from the differential navigation solution any ranging source for which $\sigma_{pr_gnd_D}$ in the Type 11 message or σ_{pr_gnd} in the Type 1 message is set to the bit pattern “1111 1111”.

3.6.8.3.1.7 The receiver shall only use a ranging source in the differential navigation solution if the time of applicability indicated by the modified Z-count in the Type 1, Type 11 or Type 101 message containing the ephemeris decorrelation parameter for that ranging source is less than 120 seconds old.

3.6.8.3.1.8 Conditions for use of data to support approach services

3.6.8.3.1.8.1 During the final stages of an approach, the receiver shall use only measurement blocks from Type 1, Type 11 or Type 101 messages that were received within the last 3.5 seconds.

Note. — *Guidance concerning time to alert is given in Attachment D, 7.5.12.3.*

3.6.8.3.1.8.2 GCID Indications.

3.6.8.3.1.8.2.1 When the active service type is A, B or C, the receiver shall use message data from a GBAS ground subsystem for guidance only if the GCID indicates 1, 2, 3 or 4 prior to initiating the final stages of an approach.

3.6.8.3.1.8.2.2 When the active service type is D, the receiver shall use message data from a GBAS ground subsystem for guidance only if the GCID indicates 2, 3 or 4 prior to initiating the final stages of an approach.

3.6.8.3.1.8.3 The receiver shall ignore any changes in GCID during the final stages of an approach.

3.6.8.3.1.8.4 The receiver shall not provide approach vertical guidance based on a particular FAS data block transmitted in a Type 4 message if the FASVAL received prior to initiating the final stages of the approach is set to “1111 1111”.

3.6.8.3.1.8.5 The receiver shall not provide approach guidance based on a particular FAS data block transmitted in a Type 4 message if the FASLAL received prior to initiating the final stages of the approach is set to “1111 1111”.

3.6.8.3.1.8.6 Changes in the values of FASLAL and FASVAL data transmitted in a Type 4 message during the final stages of an approach shall be ignored by the receiver.

3.6.8.3.1.8.7 The receiver shall use FAS data only if the FAS CRC for that data has been verified.

3.6.8.3.1.8.8 The receiver shall only use messages for which the GBAS ID (in the message block header) matches the GBAS ID in the header of the Type 4 message which contains the selected FAS data or the Type 2 message which contains the selected RSDS.

3.6.8.3.1.8.9 Use of FAS data

3.6.8.3.1.8.9.1 The receiver shall use the Type 4 messages to determine the FAS for precision approach.

3.6.8.3.1.8.9.2 The receiver shall use the Type 4 messages to determine the FAS for approaches which are supported by GBAS approach service type (GAST) A or B associated with a channel number between 20 001 and 39 999.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 259

3.6.8.3.1.8.9.3 The receiver shall use the FAS held within the on-board database for approaches which are supported by GBAS approach service type (GAST) A associated with a channel number between 40 000 and 99 999.

3.6.8.3.1.8.10 When the GBAS ground subsystem does not broadcast the Type 4 message and the selected FAS data are available to the receiver from an airborne database, the receiver shall only use messages from the intended GBAS ground subsystem.

3.6.8.3.1.9 Conditions for use of data to provide the GBAS positioning service

3.6.8.3.1.9.1 The receiver shall only use measurement blocks from Type 1 messages that were received within the last 7.5 seconds.

3.6.8.3.1.9.2 The receiver shall only use measurement blocks from Type 101 messages that were received within the last 5 seconds.

3.6.8.3.1.9.3 The receiver shall only use message data if a Type 2 message containing additional data block 1 has been received and the RSDS parameter in this block indicates that the GBAS positioning service is provided.

3.6.8.3.1.9.4 The receiver shall only use messages for which the GBAS ID (in the message block header) matches the GBAS ID in the header of the Type 2 message which contains the selected RSDS.

3.6.8.3.2 Integrity

3.6.8.3.2.1 Bounding of aircraft errors. For each satellite used in the navigation solution, the receiver shall compute a σ_{receiver} such that a normal distribution with zero mean and a standard deviation equal to σ_{receiver} bounds the receiver contribution to the corrected pseudo-range error as follows:

$$\int_y^{\infty} f(x) dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \frac{y}{\sigma} \geq 0 \text{ and}$$

$$\int_{-\infty}^{-y} f(x) dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \frac{y}{\sigma} \geq 0$$

where

$f(x)$ = probability density function of the residual aircraft pseudo-range error and

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} e^{-\frac{t^2}{2}} dt.$$

3.6.8.3.2.2 Use of GBAS integrity parameters. The aircraft element shall compute and apply the vertical, lateral and horizontal protection levels described in 3.6.5.5. If a $B_{i,j}$ parameter is set to the bit pattern “1000 0000” indicating that the measurement is not available, the aircraft element shall assume that $B_{i,j}$ has a value of zero. For any active service type, the aircraft element shall verify that the computed vertical and lateral protection levels are no larger than the corresponding vertical and lateral alert limits defined in 3.6.5.6.

3.6.8.3.3 Use of satellite ephemeris data

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 260

3.6.8.3.3.1 IOD check. The receiver shall only use satellites for which the IOD broadcast by GBAS in the Type 1 or Type 101 message matches the core satellite constellation IOD for the clock and ephemeris data used by the receiver.

3.6.8.3.3.2 CRC check. The receiver shall compute the ephemeris CRC for each core satellite constellation's ranging source used in the position solution. The computed CRC shall be validated against the ephemeris CRC broadcast in the Type 1 or Type 101 prior to use in the position solution and messages within one second of receiving a new broadcast CRC. The receiver shall immediately cease using any satellite for which the computed and broadcast CRC values fail to match.

3.6.8.3.3.3 Ephemeris error position bounds

3.6.8.3.3.3.1 Ephemeris error position bounds for GBAS approach service. If the ground subsystem provides additional data block 1 in the Type 2 messages, the aircraft element shall compute the ephemeris error position bounds defined in 3.6.5.8.1 for each core satellite constellation's ranging source used in the approach position solution within 1s of receiving the necessary broadcast parameters. The aircraft element shall verify that the computed vertical and lateral ephemeris error position bounds (VEB_j and LEB_j) are no larger than the corresponding vertical and lateral alert limits defined in 3.6.5.6.

3.6.8.3.3.3.2 *Ephemeris error position bound for the GBAS positioning service.* The aircraft element shall compute and apply the horizontal ephemeris error position bound (HEB_j) defined in 3.6.5.8.2 for each core satellite constellation's ranging source used in the positioning service position solution.

3.6.8.3.4 Message loss

3.6.8.3.4.1 For airborne equipment operating with GAST C as the active service type, the receiver shall provide an appropriate alert if no Type 1 message was received during the last 3.5 seconds.

3.6.8.3.4.2 For airborne equipment operating with GAST A or B as the active service type, the receiver shall provide an appropriate alert if no Type 1 and no Type 101 message was received during the last 3.5 seconds.

3.6.8.3.4.3 For the airborne equipment operating with GAST D as the active service type, the receiver shall provide an appropriate alert or modify the active service type if any of the following conditions are met:

- a) The computed position solution is less than 200 ft above the LTP/FTP for the selected approach and no Type 1 message was received during the last 1.5 seconds.
- b) The computed position solution is less than 200 ft above the LTP/FTP for the selected approach and no Type 11 message was received during the last 1.5 seconds.
- c) The computed position solution is 200 ft or more above the LTP/FTP of the selected approach and no Type 1 message was received during the last 3.5 seconds.
- d) The computed position solution is 200 ft or more above the LTP/FTP of the selected approach and no Type 11 message was received during the last 3.5 seconds.

3.6.8.3.4.4 For the GBAS positioning service using Type 1 messages, the receiver shall provide an appropriate alert if no Type 1 message was received during the last 7.5 seconds.

3.6.8.3.4.5 For the GBAS positioning service using Type 101 messages, the receiver shall provide an appropriate alert if no Type 101 message was received during the last 5 seconds.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

3.6.8.3.5 Airborne pseudo-range measurements

3.6.8.3.5.1 Carrier smoothing for airborne equipment. Airborne equipment shall utilize the standard 100-second carrier smoothing of code phase measurements defined in 3.6.5.1. During the first 100 seconds after filter start-up, the value of α shall be either:

- a) a constant equal to the sample interval divided by 100 seconds; or
- b) a variable quantity defined by the sample interval divided by the time in seconds since filter start-up.

3.6.8.3.5.2 *Carrier smoothing of airborne equipment operating with GAST D as the active service type.* Airborne equipment operating with GAST D as the active service type, shall utilize 30-second carrier smoothing of code phase measurements as defined in 3.6.5.1.

Note.— For equipment that supports GAST D, two set of smoothed pseudo-ranges are used. The form of the smoothing filter given in section 3.6.5.1 is the same for both sets, and only the time constant differs (i.e. 100 seconds and 30 seconds). Guidance concerning carrier smoothing for GAST D is given in Attachment D, 7.19.3.

3.6.8.3.6 *Service type specific differential position solution requirements.* The airborne equipment shall compute all position solutions in a manner that is consistent with the protocols for application of the data (section 3.6.5.5.1.1.2).

Note.— The general form for the weighting used in the differential position solution is given in 3.6.5.5.1.1.2. Exactly which information from the ground subsystem is used in the differential position solution depends on the type of service (i.e. positioning service vs. approach service) and the active approach service type. The specific requirements for each service type are defined in RTCA DO-253D. Additional information concerning the normal processing of position information is given in Attachment D, 7.19.

3.7 Resistance to interference

3.7.1 Performance Objectives

Note 1.— For GNSS receivers not using differential corrections from an augmentation system, the resistance to interference is measured with respect to the following core satellite constellation performance parameters:

	<i>Tracking error (1 sigma)</i>
<i>GPS L1 (single-frequency equipment)</i>	<i>0.36 m</i>
<i>GPS L1 (dual-frequency equipment)</i>	<i>0.15 m</i>
<i>GPS L5</i>	<i>0.15 m</i>
<i>GPS L1-L5**</i>	<i>0.40 m</i>
<i>GLONASS L1OF</i>	<i>0.80 m</i>
<i>GLONASS L1OC</i>	<i>0.30 m</i>
<i>GLONASS L3OC</i>	<i>0.10 m</i>
<i>GLONASS L1OC-L3OC**</i>	<i>0.65 m</i>
<i>Galileo E1-E5a**</i>	<i>0.40 m</i>

	<i>Tracking error (1 sigma)</i>
<i>Galileo E1</i>	<i>0.15 m</i>
<i>Galileo E5a</i>	<i>0.15 m</i>
<i>BDS B1I</i>	<i>0.60 m</i>
<i>BDS B1C</i>	<i>0.20 m</i>
<i>BDS B2a</i>	<i>0.15 m</i>
<i>BDS B1C-B2a**</i>	<i>0.40 m</i>

* *The accuracy budget for the tracking error is specified for smoothed measurements.*
** *Refers to dual-frequency ionosphere-free pseudo-range measurements.*

Note 2- This tracking error neither includes contributions due to signal propagation such as multipath, tropospheric and ionospheric effects nor ephemeris and GPS , ~~and~~ GLONASS, Galileo and BDS satellite clock errors.

Note 3 - For SBAS receivers, the resistance to interference is measured with respect to parameters specified in 3.5.8.2.1, ~~and~~ 3.5.8.4.1 and 3.5.15.3.2.

Note 4 - For GBAS receivers, the resistance to interference is measured with respect to parameters specified in 3.6.7.1.1 and 3.6.8.2.1.

Note 5 - The signal levels specified in this section are defined at the antenna port. Assumed maximum aircraft antenna gain in the lower hemisphere is -10 dBic.

Note 6 - The performance requirements are to be met in the interference environments defined below. This defined interference environment is relaxed during initial acquisition of GNSS signals when the receiver cannot take advantage of a steady-state navigation solution to aid signal acquisition.

Note 7.— If not specified, the equipment performance objectives and requirements specified for a particular constellation apply whether the equipment supports only that constellation (single constellation equipment) or that constellation and other constellation(s) (multiple constellation equipment).

3.7.2 Continuous (CW) Interference

3.7.2.1 GPS L1 and SBAS L1 Receiver

Note.— Less interference power is tolerated by the interference thresholds for GPS L1 and SBAS L1 receivers than for the dual-frequency L1/L5 receivers in the band 1 480 – 1 565 MHz described in 3.7.2.3.

3.7.2.1.1 After steady-state navigation has been established, GPS L1 and SBAS L1 receivers shall meet the performance objectives with CW interfering signals present with a power level at the antenna port equal to the interference thresholds specified in Table B-83 and shown in Figure B-15 and with a desired GPS L1 and SBAS L1 signal level of -164 dBW at the antenna port.

3.7.2.1.2 During initial acquisition of the GPS L1 and SBAS L1 signals prior to steady-state navigation, GPS L1 and SBAS L1 receivers shall meet the performance objectives with interference thresholds 6 dB less than those specified in Table B-83.

3.7.2.2 GLONASS Receiver

3.7.2.2.1 After steady-state navigation has been established, GLONASS FDMA signal receivers in L1 band (except those identified in 3.7.2.2.1.1) shall meet the performance objectives with CW interfering signals present with a power level at the antenna port equal to the interference thresholds specified in Table B-84 and shown in Figure B-16 and with a desired signal level -166.5 dBW at the antenna port.

Table B-156. CW interference thresholds for GPS L1 and SBAS L1 receivers in steady-state navigation

<i>Frequency range f_i of the interference signal</i>	<i>Interference thresholds for receivers in steady-state navigation</i>
$f_i \leq 1\ 315$ MHz	-4.5 dBW
$1\ 315$ MHz $< f_i \leq 1\ 500$ MHz	Linearly decreasing from -4.5 dBW to -38 dBW
$1\ 500$ MHz $< f_i \leq 1\ 525$ MHz	Linearly decreasing from -38 dBW to -42 dBW
$1\ 525$ MHz $< f_i \leq 1\ 565.42$ MHz	Linearly decreasing from -42 dBW to -150.5 dBW
$1\ 565.42$ MHz $< f_i \leq 1\ 585.42$ MHz	-150.5 dBW
$1\ 585.42$ MHz $< f_i \leq 1\ 610$ MHz	Linearly increasing from -150.5 dBW to -60 dBW
$1\ 610$ MHz $< f_i \leq 1\ 618$ MHz	Linearly increasing from -60 dBW to -42 dBW*
$1\ 618$ MHz $< f_i \leq 2\ 000$ MHz	Linearly increasing from -42 dBW to -8.5 dBW*
$1\ 618$ MHz $< f_i \leq 1\ 626.5$ MHz	Linearly increasing from -60 dBW to -22 dBW**
$1\ 626.5$ MHz $< f_i \leq 2\ 000$ MHz	Linearly increasing from -22 dBW to -8.5 dBW**
$f_i > 2\ 000$ MHz	-8.5 dBW

* Applies to aircraft installations where there are no on-board satellite communications.
** Applies to aircraft installations where there are on-board satellite communications.

3.7.2.2.1.1 After steady-state navigation has been established, GLONASS FDMA signals receivers in L1 band used for all phases of flight (excluding those used for the precision approach phase of flight) and put into operation before 1 January 2017 shall meet the performance objectives with CW interfering signals present with a power level at the antenna port 3 dB less than the interference thresholds specified in Table B-84 and shown in Figure B-16 and with a desired signal level of -166.5 dBW at the antenna port.

Table B-157. CW interference thresholds for GLONASS FDMA signals receivers in L1 band in steady-state navigation

<i>Frequency range f_i of the interference signal</i>	<i>Interference thresholds for receivers in steady-state navigation</i>
$f_i \leq 1\,315$ MHz	-4.5 dBW
$1\,315$ MHz < $f_i \leq 1\,562.15625$ MHz	Linearly decreasing from -4.5 dBW to -42 dBW
$1\,562.15625$ MHz < $f_i \leq 1\,583.65625$ MHz	Linearly decreasing from -42 dBW to -80 dBW
$1\,583.65625$ MHz < $f_i \leq 1\,592.9525$ MHz	Linearly decreasing from -80 dBW to -149 dBW
$1\,592.9525$ MHz < $f_i \leq 1\,609.36$ MHz	-149 dBW
$1\,609.36$ MHz < $f_i \leq 1\,613.65625$ MHz	Linearly increasing from -149 dBW to -80 dBW
$1\,613.65625$ MHz < $f_i \leq 1\,635.15625$ MHz	Linearly increasing from -80 dBW to -42 dBW*
$1\,613.65625$ MHz < $f_i \leq 1\,626.15625$ MHz	Linearly increasing from -80 dBW to -22 dBW**
$1\,635.15625$ MHz < $f_i \leq 2\,000$ MHz	Linearly increasing from -42 dBW to -8.5 dBW*
$1\,626.15625$ MHz < $f_i \leq 2\,000$ MHz	Linearly increasing from -22 dBW to -8.5 dBW**
$f_i > 2\,000$ MHz	-8.5 dBW

* Applies to aircraft installations where there are no on-board satellite communications.
** Applies to aircraft installations where there is on-board satellite communications.

3.7.2.2.1.2 After steady-state navigation has been established, GLONASS CDMA signals receivers in L1 and L3 bands shall meet the performance objectives with CW interfering signals present with a power level at the antenna port equal to the interference thresholds specified in Tables TAB-01 and TAB-02 and shown in Figures FIG-01 and FIG-02 and with a desired signal level of -161.5 dBW at the antenna port.

$f_i \leq 908$ MHz	-4.5 dBW
908 MHz < $f_i \leq 1\ 155.775$ MHz	Linearly decreasing from -4.5 dBW to -42 dBW
1 155.775 MHz < $f_i \leq 1\ 178.775$ MHz	Linearly decreasing from -42 dBW to -73 dBW
1 178.775 MHz < $f_i \leq 1\ 191.775$ MHz	Linearly decreasing from -73 dBW to -143 dBW
1 191.775 MHz < $f_i \leq 1\ 212.275$ MHz	-143 dBW
1 212.275 MHz < $f_i \leq 1\ 224.875$ MHz	Linearly increasing from -143 dBW to -73 dBW
1 224.875 MHz < $f_i \leq 1\ 244.375$ MHz	Linearly increasing from -73 dBW to -42 dBW
1 244.375 MHz < $f_i \leq 1\ 492.125$ MHz	Linearly increasing from -42 dBW to -4.5 dBW
$f_i > 1\ 492.125$ MHz	-4.5 dBW

3.7.2.2.2 During initial acquisition of the GLONASS FDMA signals in L1 band prior to steady-state navigation, GLONASS receivers shall meet the performance objectives with interference thresholds 6 dB less than those specified in Table B-84.

3.7.2.3.1 During initial L5/E5a acquisition prior to steady-state navigation, and after steady-state navigation has been established, DFMC SBAS receivers processing signals centred on L1/E1 and L5/E5a frequencies shall meet the performance objectives with CW interfering signals present with a power level at the antenna port equal to the interference thresholds specified in Table TAB-03 and shown in Figure FIG-03, and with a desired SBAS L5 signal level of -162.5 dBW, with a desired GPS L5 signal level of -159.4 dBW, and with a desired Galileo E5a signal level of -160.4 dBW at the antenna port.

3.7.2.3.2 After steady-state navigation has been established, DFMC SBAS receivers processing signals centred on L1/E1 and L5/E5a frequencies shall meet the performance objectives with CW interfering signals present with a power level at the antenna port equal to the interference thresholds specified in Table TAB-03 and shown in Figure FIG-03, and with a desired GPS L1 and SBAS L1 signal level of -163 dBW and with a desired Galileo E1 signal level of -162.25 dBW at the antenna port. During initial L1/E1 acquisition, DFMC SBAS receivers shall meet the performance objectives with interference levels that are 6 dB below what is specified in Table TAB-03.

Note.— CW interference thresholds for DMFC SBAS receivers determine the interference power levels applicable for the frequency ranges defined in Table TAB-03.

Table B-160. CW interference thresholds for GPS L1/L5, Galileo E1/E5a and DFMC SBAS receivers

<i>Frequency range f_i of the interference signal</i>	<i>Interference thresholds for receivers</i>
$f_i \leq 1\ 000\ \text{MHz}$	-21 dBW
$1\ 000\ \text{MHz} < f_i \leq 1\ 100.45\ \text{MHz}$	Linearly decreasing from -21 dBW to -44 dBW

$1\ 585.42\ \text{MHz} < f_i \leq 1\ 610\ \text{MHz}$	Linearly increasing from -150.5 dBW to -60 dBW
$1\ 610\ \text{MHz} < f_i \leq 1\ 618\ \text{MHz}$	Linearly increasing from -60 dBW to -42 dBW
$1\ 618\ \text{MHz} < f_i \leq 2\ 000\ \text{MHz}$	Linearly increasing from -42 dBW to -12 dBW*
$1\ 618\ \text{MHz} < f_i \leq 1\ 626.5\ \text{MHz}$	Linearly increasing from -42 dBW to -22 dBW*
$1\ 626.5\ \text{MHz} < f_i \leq 2\ 000\ \text{MHz}$	Linearly increasing from -22 dBW to -12 dBW**
$f_i > 2\ 000\ \text{MHz}$	-12 dBW**

* Applies to aircraft installations where there are no on-board satellite communications.
** Applies to aircraft installations where there are on-board satellite communications.

3.7.2.4 BDS RECEIVERS

3.7.2.4.1 After steady-state navigation has been established, BDS B1I receivers shall meet the performance objectives with CW interfering signals present with a power level at the antenna port equal to the interference thresholds specified in Table TAB-04B and shown in Figure FIG-04A and with a desired BDS signal level of -164.5 dBW at the antenna port. During initial acquisition prior to steady-state navigation, BDS B1I receivers shall meet the performance objectives with 6 dB less than those specified in Table TAB-04B.

3.7.2.4.2 After steady-state navigation has been established, BDS B1C/B2a receivers shall meet the performance objectives with a power level at the antenna port equal to the interference thresholds specified in Table TAB-04C and shown in Figure FIG-04B and with desired BDS signal levels of -163.5 dBW for B1C and -160.5 dBW for B2a at the antenna port. During initial acquisition prior to steady-state navigation, BDS B1C/B2a receivers shall meet the performance objectives with 6 dB less than those specified in Table TAB-04C.

3.7.3 Band-limited noise-like interference

3.7.3.1 GPS L1 and SBAS L1 receiver

3.7.3.1.1 After steady-state navigation has been established, GPS L1 and SBAS L1 receivers shall meet the performance objectives with noise-like interfering signals present in the frequency range of $1\ 575.42\ \text{MHz} \pm Bw_i/2$ and with power levels at the antenna port equal to the interference thresholds specified in Table B-85 and shown in Figure B-17 and with the desired signal level of $-164\ \text{dBW}$ at the antenna port.

Note.— Bw_i is the equivalent noise bandwidth of the interference signal.

3.7.3.1.2 During initial acquisition of the GPS and SBAS signals prior to steady-state navigation, GPS L1 and SBAS L1 receivers shall meet the performance objectives with interference thresholds 6 dB less than those specified in Table B-85.

3.7.3.2 GLONASS Receiver

3.7.3.2.1 After steady-state navigation has been established, GLONASS FDMA signals receivers in L1 band (except those identified in 3.7.3.2.1.1) shall meet the performance objectives while receiving noise-like interfering signals in the frequency band $f_k \pm Bw_i/2$, with power levels at the antenna port equal to the interference thresholds specified in Table B-86 and shown in Figure B-18 and with a desired signal level of $-166.5\ \text{dBW}$ at the antenna port.

3.7.3.2.1.1 After steady-state navigation has been established, GLONASS FDMA signals receivers in L1 band used for all phases of flight (excluding those used for the precision approach phase of flight) and put into operation before 1 January 2017 shall meet the performance objectives while receiving noise-like interfering signals in the frequency band $f_k \pm Bw_i/2$, with power levels at the antenna port 3 dB less than the interference thresholds specified in Table B-86 and shown in Figure B-18 and with a desired signal level of $-166.5\ \text{dBW}$ at the antenna port.

Note.— f_k is the centre frequency of a GLONASS channel with $f_k = 1\ 602\ \text{MHz} + k \times 0.5625\ \text{MHz}$ and $k = -7$ to $+6$ as defined in Table B-16 and Bw_i is the equivalent noise bandwidth of the interference signal.

3.7.3.2.1.2 After steady-state navigation has been established, GLONASS CDMA signals receivers in L1 and L3 bands shall meet the performance objectives while receiving noise-like interfering signals in the frequency band $f_k \pm Bw_i/2$, with power levels at the antenna port equal to the interference thresholds specified in Tables TAB-05 and TAB-06 and shown in Figures FIG-05 and FIG-06 and with a desired signal level of $-161.5\ \text{dBW}$ at the antenna port.

3.7.3.2.2 During initial acquisition of the GLONASS FDMA signals in L1 band prior to steady-state navigation, GLONASS receivers shall meet the performance objectives with interference thresholds 6 dB less than those specified in Table B-86.

3.7.3.2.2.1 During initial acquisition of the GLONASS CDMA signals in L1 and L3 bands prior to steady-state navigation, GLONASS receivers shall meet the performance objectives with interference thresholds 6 dB less than those specified in Tables B-163 and B-164.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

Table B-163. Interference threshold for band-limited noise-like interference to GLONASS CDMA L1 signals receivers in L1 band in steady-state navigation

<i>Interference bandwidth</i>	<i>Interference threshold</i>
0 Hz < Bw _i ≤ 1 kHz	-149 dBW
1 kHz < Bw _i ≤ 10 kHz	Linearly increasing from -149 to -143 dBW
10 kHz < Bw _i ≤ 0.5 MHz	-143 dBW
0.5 MHz < Bw _i ≤ 10 MHz	Linearly increasing from -143 to -130 dBW
10 MHz < Bw _i	-130 dBW

Table B-164. Interference threshold for band-limited noise-like interference to GLONASS CDMA signals receivers in L3 band in steady-state navigation

<i>Interference bandwidth</i>	<i>Interference threshold</i>
0 Hz < Bw _i ≤ 1 kHz	-143 dBW
1 kHz < Bw _i ≤ 1 MHz	Linearly increasing from -143 to -140 dBW
1 MHz < Bw _i ≤ 20 MHz	Linearly increasing from -140 to -126.9 dBW
20 MHz < Bw _i	-126.9 dBW

3.7.3.3 GPS L1/L5, GALILEO E1/E5A and DFMC SBAS Receiver

3.7.3.3.1 During initial L5/E5a acquisition prior to steady-state navigation, and after steady-state navigation has been established, GPS L1/L5, Galileo E1/E5a and DFMC SBAS receivers processing signals centred on L1/E1 and L5/E5a frequencies shall meet the performance objectives with noise-like interfering signals present in the frequency range of $1\ 176.45\ \text{MHz} \pm Bw_i/2$ and with power levels at the antenna port equal to the interference thresholds specified in Table TAB-07 and shown in Figure FIG-07 and with a desired SBAS L5 signal level of -162.5 dBW, with a desired GPS L5 level of -159.4 dBW and with a desired Galileo E5a level of -160.4 dBW at the output of the antenna.

Note.— Bw_i is the equivalent noise bandwidth of the interference signal.

3.7.3.3.2 After steady-state navigation has been established, GPS L1/L5, Galileo E1/E5a and DFMC SBAS receivers processing signals centred on L1/E1 and L5/E5a frequencies shall meet the performance objectives with noise-like interfering signals present in the frequency range of $1\ 575.42\ \text{MHz} \pm Bw_i/2$ and with power levels at the antenna port equal to the interference thresholds specified in Table B-85 and shown in Figure B-17 and with the desired GPS and SBAS L1 signal levels of -163 dBW and with the desired Galileo E1 signal level of -162.25 dBW at the antenna port. During initial L1/E1 acquisition, DFMC SBAS receivers shall meet the performance objectives with interference thresholds 6 dB less than those specified in Table B-85.

Note.— Bw_i is the equivalent noise bandwidth of the interference signal.

Table B-165. Interference threshold for band-limited noise-like interference to GPS L1/L5, Galileo E1/E5A and DFMC SBAS receivers

<i>Interference bandwidth</i>	<i>Interference threshold for receivers</i>
0 Hz < Bw _i ≤ 1kHz	-145.0 dBW
1 kHz < Bw _i ≤ 10 kHz	Linearly increasing from -145.0 to -137.5 dBW
10 kHz < Bw _i ≤ 100 kHz	Linearly increasing from -137.5 to -133.9 dBW
100 kHz < Bw _i ≤ 1 MHz	Linearly increasing from -133.9 to -133.0 dBW
1 MHz < Bw _i ≤ 10 MHz	Linearly increasing from -133.0 to -131.7 dBW*
10 MHz < Bw _i ≤ 40 MHz	Linearly increasing from -131.7 to -127.0 dBW*

* The interference threshold is not to exceed -134.0 dBW/MHz in the frequency range 1 176.45 ±10 MHz.

3.7.3.4 BDS Receiver

3.7.3.4.1 After steady-state navigation has been established, BDS B1I receivers shall meet the performance objectives with noise like interfering signals present in the frequency range of 1561.098 MHz ±Bw_i/2 and with power levels at the antenna port equal to the interference thresholds specified in Table TAB-08A and shown in Figure FIG-08A and with a desired B1I signal level of -164.5 dBW at the output of the antenna. During initial acquisition of the BDS B1I signals prior to steady-state navigation, BDS receivers shall meet the performance objectives with interference thresholds 6 dB less than those specified in Table TAB-08A.

Note.— Bw_i is the equivalent noise bandwidth of the interference signal.

3.7.3.4.2 After steady-state navigation has been established, BDS B1C receivers shall meet the performance objectives with noise-like interfering signals present in the frequency range of 1 575.42 MHz ±Bw_i/2 and with power levels at the antenna port equal to the interference thresholds specified in Table TAB-08B and shown in Figure FIG-08B and with a desired B1C signal level of -163.5 dBW at the output of the antenna. During initial acquisition of the BDS B1C signals prior to steady-state navigation, BDS receivers shall meet the performance objectives with interference thresholds 6 dB less than those specified in Table TAB-08B.

Note.— Bw_i is the equivalent noise bandwidth of the interference signal.

Table B-166. Interference threshold for band-limited noise-like interference to BDS B1I receivers in steady-state navigation

<i>Interference bandwidth</i>	<i>Interference threshold for receivers in steady-state navigation</i>
0 Hz < Bw _i ≤ 700 Hz	-150.5 dBW
700 Hz < Bw _i ≤ 10 kHz	Linearly increasing from -150.5 dBW to -143.5 dBW
10 kHz < Bw _i ≤ 100 kHz	Linearly increasing from -143.5 dBW to -140.5 dBW
100 kHz < Bw _i ≤ 1 MHz	-140.5 dBW
1 MHz < Bw _i ≤ 4.096 MHz	Linearly increasing from -140.5 dBW to -134.4 dBW
4.096 MHz < Bw _i ≤ 10 MHz	Linearly increasing from -134.4 dBW to -126 dBW
10 MHz < Bw _i	-126.0 dBW

* The interference threshold is not to exceed -140.5 dBW/MHz in the frequency range 1 561.098 ± 2.046 MHz.

Table B-167. Interference threshold for band-limited noise-like interference to BDS B1C receivers in steady-state navigation

<i>Interference bandwidth</i>	<i>Interference threshold for receivers in steady-state navigation</i>
0 Hz < Bw _i ≤ 700 Hz	-150.5 dBW
700 Hz < Bw _i ≤ 10 kHz	Linearly increasing from -150.5 to -143.5 dBW
10 kHz < Bw _i ≤ 100 kHz	Linearly increasing from -143.5 to -140.5 dBW
100 kHz < Bw _i ≤ 1 MHz	-140.5 dBW
1 MHz < Bw _i ≤ 20 MHz	Linearly increasing from -140.5 to -127.5 dBW*
20 MHz < Bw _i ≤ 30 MHz	Linearly increasing from -127.5 to -121.1 dBW*
30 MHz < Bw _i ≤ 40 MHz	Linearly increasing from -121.1 to -119.5 dBW*
40 MHz < Bw _i	-119.5 dBW*

* The interference threshold is not to exceed -140.5 dBW/MHz in the frequency range 1 575.42 ±10 MHz.

3.7.3.4.3 After steady-state navigation has been established, BDS B2a receivers shall meet the performance objectives with noise-like interfering signals present in the frequency range of 1 176.45 MHz ±Bw_i/2 and with power levels at the antenna port equal to the interference thresholds specified in Table TAB-08C and shown in Figure FIG-08C and with a desired B2a signal level of -160.5 dBW at the output of the antenna. During initial acquisition of the BDS B2a signals prior to steady-state navigation, BDS receivers shall meet the performance objectives with interference thresholds 6 dB less than those specified in Table TAB-08C.

Note.— Bw_i is the equivalent noise bandwidth of the interference signal.

Table B-168. Interference threshold for band-limited noise-like interference to BDS B2a receivers in steady-state navigation

<i>Interference bandwidth</i>	<i>Interference threshold for receivers in steady-state navigation</i>
0 Hz < Bw _i ≤ 1kHz	-145.0 dBW
1 kHz < Bw _i ≤ 10 kHz	Linearly increasing from -145.0 to -137.5 dBW
10 kHz < Bw _i ≤ 100 kHz	Linearly increasing from -137.5 to -133.9 dBW
100 kHz < Bw _i ≤ 1 MHz	Linearly increasing from -133.9 to -133.0 dBW
1 MHz < Bw _i ≤ 10 MHz	Linearly increasing from -133.0 to -131.7 dBW*
10 MHz < Bw _i ≤ 40 MHz	Linearly increasing from -131.7 to -127.0 dBW*

* The interference threshold is not to exceed -134.0 dBW/MHz in the frequency range 1 176.45 ±10 MHz.

3.7.3.5 Pulsed interference. After steady-state navigation has been established, the GNSS receiver shall meet the performance objectives while receiving pulsed interference signals with characteristics according to Table B-87 where the interference threshold is defined at the antenna port.

3.7.3.6 GNSS receivers shall not output misleading information in the presence of interference including interference levels above those specified in 3.7.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Technical provision for GNSS	Appendix-B	Page: 272

Note - Guidance material on this requirement is given in Attachment D, 10.5.

3.8 GNSS aircraft satellite receiver antenna

3.8.1 Antenna coverage. The GNSS antenna shall meet the performance requirements for the reception of GNSS satellite signals from 0 to 360 degrees in azimuth and from 0 to 90 degrees in elevation relative to the horizontal plane of an aircraft in level flight.

3.8.2 *Antenna gain*. The minimum passive antenna element gain for single-frequency antennas shall not be less than that shown in Table B-88A for the specified elevation angle above the horizon. For these antennas, the maximum passive antenna element gain shall not exceed +4 dBic for elevation angles above 5 degrees. The minimum passive antenna element gains at both frequencies for dual-frequency antennas shall comply with Table B-88B for the specified elevation angles above the horizon. For these antennas, the maximum passive antenna element gain shall be limited to +4 dBic for elevation angles above 75 degrees.

3.8.3 Polarization. The GNSS antenna polarization shall be right-hand circular (clockwise with respect to the direction of propagation).

3.8.3.1 *Axial ratio*. For single-frequency antennas, the axial ratio shall not exceed 3.0 dB as measured at boresight. For dual-frequency antennas, the axial ratio shall be less than or equal to 3 dB over the operating frequency range as measured in a region extending from boresight down to 40 degrees off boresight across all azimuth angles.

3.9 Cyclic redundancy check

Each CRC shall be calculated as the remainder, $R(x)$, of the Modulo-2 division of two binary polynomials as follow

$$\left\{ \frac{[x^k M(x)]}{G(x)} \right\}_{\text{mod } 2} = Q(x) + \frac{R(x)}{G(x)}$$

where

- k = the number of bits in the particular CRC;
- $M(x)$ = the information field, which consists of the data items to be protected by the particular CRC represented as a polynomial;
- $G(x)$ = the generator polynomial specified for the particular CRC;
- $Q(x)$ = the quotient of the division; and
- $R(x)$ = the remainder of the division, contains the CRC:

$$R(x) = \sum_{i=1}^k r_i x^{k-i} = r_1 x^{k-1} + r_2 x^{k-2} + \dots + r_k x^0$$

Table B-169. Interference threshold for band-limited noise-like interference to GPS L1 and SBAS L1 receivers in steady-state navigation

<i>Interference bandwidth</i>	<i>Interference threshold for receivers in steady-state navigation</i>
0 Hz < Bw _i ≤ 700 Hz	-150.5 dBW
700 Hz < Bw _i ≤ 10 kHz	Linearly increasing from -150.5 to -143.5 dBW
10 kHz < Bw _i ≤ 100 kHz	Linearly increasing from -143.5 to -140.5 dBW
100 kHz < Bw _i ≤ 1 MHz	-140.5 dBW
1 MHz < Bw _i ≤ 20 MHz	Linearly increasing from -140.5 to -127.5 dBW*
20 MHz < Bw _i ≤ 30 MHz	Linearly increasing from -127.5 to -121.1 dBW*
30 MHz < Bw _i ≤ 40 MHz	Linearly increasing from -121.1 to -119.5 dBW*
40 MHz < Bw _i	-119.5 dBW*

** The interference threshold is not to exceed -140.5 dBW/MHz in the frequency range 1 575.42 ±10 MHz.*

Table B-170. Interference threshold for band-limited noise-like interference to GLONASS FDMA signals receivers in L1 band in steady-state navigation

<i>Interference bandwidth</i>	<i>Interference threshold</i>
0 Hz < Bw _i ≤ 1 kHz	-149 dBW
1 kHz < Bw _i ≤ 10 kHz	Linearly increasing from -149 to -143 dBW
10 kHz < Bw _i ≤ 0.5 MHz	-143 dBW
0.5 MHz < Bw _i ≤ 10 MHz	Linearly increasing from -143 to -130 dBW
10 MHz < Bw _i	-130 dBW

Table B-171. Interference thresholds for pulsed interference

Figure B-4. HOW format

Notes:

1. To aid in rapid ground lock-on, the HOW of each subframe contains a truncated TOW count.
2. The HOW is the second word in each subframe.
3. The HOW message TOW count consists of the 17 MSBs of the actual TOW count at the start of the next subframe.
4. To convert from the HOW message TOW count to the actual count at the start of the next subframe, multiply by four.
5. The first subframe starts synchronously with the end/start of each epoch.

	Determination of integrity and continuity of service objectives using risk tree method	Attachment A	Page: 1

ATTACHMENT A. DETERMINATION OF INTEGRITY AND CONTINUITY OF SERVICE OBJECTIVES USING THE RISK TREE METHOD

1. The risk tree method is a graphical method of expressing the logical relationship between a particular failure condition and the causes or failures leading to this condition. It is an application of fault tree analysis being used in the aerospace industry.

1.1 The method employs a set of logic symbols to show the relationship between the various causes of failure. The following symbols are used in this guidance material.

The “AND” gate describes the logical operation whereby the coexistence of all input events is required to produce the output event.

The “OR” gate defines a situation whereby the output event will exist if one or more of the input events exist.

The rectangle identifies an event that results from the combination of fault or failure events through the input logic gate.

The circle describes a primary failure event that requires no further development. Frequency and mode of failure of items so identified are derived from empirical data.

1.2 The method gives a visual representation of sequences and combinations of events leading to the top failure event. The method can also be used to determine the probability of the top event occurring, provided that the probabilities of the individual events are known or can be estimated. In the case of simple fault trees probabilities can be directly calculated, but care must be taken if the primary failure events are not independent, i.e. if failure events are common to more than one path.

1.3 In this guidance material the acceptable probability of the top level event occurring is determined by the risk allocation and the fault tree is used to further partition the risk into integrity and continuity of service risks. Therefore, the term “risk tree” is used rather than “fault tree”.

2.A generic risk tree for aircraft landing operations is given in Figure A-1. The top event for this tree is taken to be the loss of the aircraft due to a failure of the non-aircraft guidance system. The causes of this event are either an integrity failure of the primary non-aircraft guidance equipment or a continuity of service (COS) failure of the non-aircraft guidance system (i.e. both the primary system and any secondary system used to support a discontinued approach/missed approach). The primary non-aircraft guidance system is considered to have a number of elements, 1 to N, for example azimuth, elevation and DME/P in the case of MLS. The secondary guidance system may be an alternative non-aircraft system, or in some cases an aircraft navigation system such as an inertial reference system.

2.1 The following probabilities can be defined:

P_a = Probability of aircraft loss due to a failure of the non-aircraft guidance system.

P_b = Probability of aircraft loss due to primary guidance integrity failure.

P_c = Probability of aircraft loss due to COS failure.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

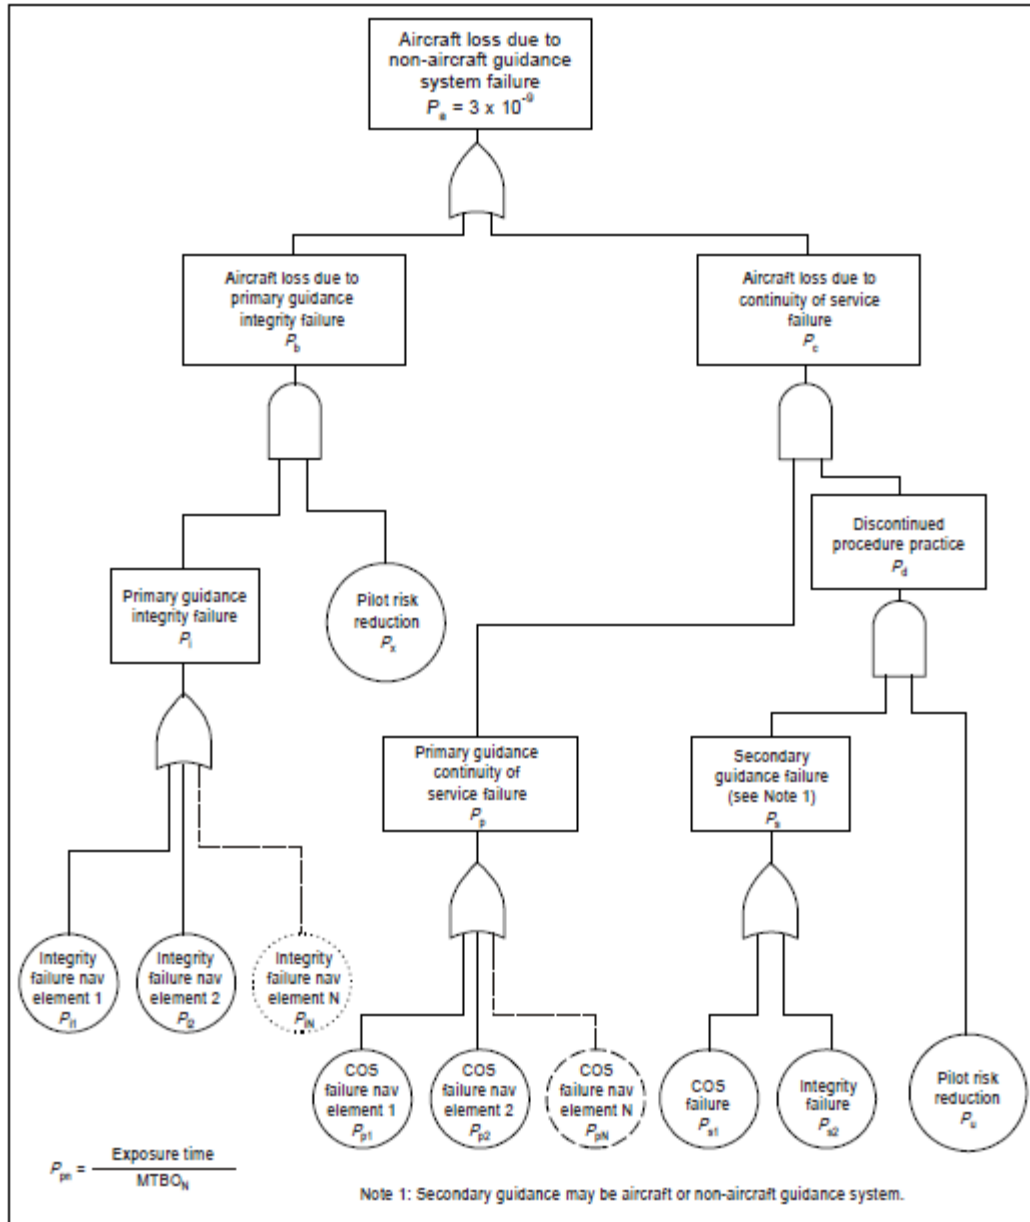

Figure A-1. Generic risk tree

	Aeronautical telecommunication-V1	BCAR-10	
	Determination of integrity and continuity of service objectives using risk tree method	Attachment A	Page: 3

P_x = Probability that the pilot is unable to detect and intervene successfully following a primary guidance integrity failure. This risk reduction factor is only relevant in those cases where an integrity failure of the guidance system may be detected by the pilot, e.g. at decision height in a Category I ILS approach.

P_p = Probability of primary guidance COS failure.

P_d = Probability of aircraft loss during a discontinued approach/missed approach procedure.

P_i = Probability of primary guidance integrity failure.

P_{iN} = Probability of integrity failure in Nav element N.

P_{pN} = Probability of COS failure in Nav element N.

P_s = Probability of aircraft loss during a discontinued approach/missed approach with secondary guidance.

P_{s1} = Probability of secondary guidance COS failure.

P_{s2} = Probability of secondary guidance integrity failure.

P_u = Probability that the pilot is unable to intervene successfully following primary guidance COS failure with no secondary guidance available.

Where:

$$P_a = P_b + P_c$$

$$P_b = P_i \times P_x$$

$$P_i = P_{i1} + P_{i2} + \dots P_{iN}$$

$$P_c = P_p \times P_d$$

$$P_p = P_{p1} + P_{p2} + \dots P_{pN}$$

$$P_d = P_s \times P_u$$

$$P_s = P_{s1} + P_{s2}$$

2.2 The acceptable probability of the top event, P_a , can be determined by partitioning the global risk factor for the approach and landing operation to the various classes of accident. Using this method an acceptable value for P_a of 3×10^{-9} has been determined. This is consistent with the smallest probability that can be assigned to each ground navigation element, which is 1×10^{-9} (normally divided equally between integrity and COS failures).

2.3 The risk analysis above assumes no equipment design errors.

	Strategy for introduction and application of non-visual aids to approach and landing	Attachment B	Page: 1

ATTACHMENT B. STRATEGY FOR INTRODUCTION AND APPLICATION OF NON-VISUAL AIDS TO APPROACH AND LANDING (see Chapter 2, 2.1)

1.Introduction

1.1 Various elements have an influence on all weather operations in terms of safety, efficiency and flexibility. The evolution of new techniques requires a flexible approach to the concept of all weather operations to obtain full benefits of technical development. To create this flexibility a strategy enables, through identification of its objectives and thoughts behind the strategy, incorporation of new technical developments or ideas into this strategy. The strategy does not assume a rapid transition to a single globally established system or selection of systems to support approach and landing operations.

1.2 The strategy addresses the application of non-visual aids to approach and landing with vertical guidance (APV) and precision approach and landing operations.

2.Objectives of strategy

The strategy must:

- a) maintain at least the current safety level of all weather operations;
- b) retain at least the existing level or planned improved level of service;
- c) support lateral and vertical path guidance as outlined in Resolution A37-11;
- d) maintain global interoperability;
- e) provide regional flexibility based on coordinated regional planning;
- f) support infrastructure investment planning cycles;
- g) be maintained by periodic review; and
- h) take account of economic, operational and technical issues.

3. Considerations

3.1 General

The following considerations are based on the assumption that the operational requirement and the required commitment are available and the required effort is applied.

3.2 (Reserved) ILS-related considerations

3.3(Reserved) MLS-related considerations

3.4 GNSS-related considerations

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Strategy for introduction and application of non-visual aids to approach and landing	Attachment B	Page: 2

- a) Standards and Recommended Practices (SARPs) are in place for GNSS with augmentation to support APV and Category I precision approach;
- b) GNSS with satellite-based augmentation system (SBAS) for APV and Category I precision approach operations is operational ;
- c) GNSS with ground-based augmentation system (GBAS) for Category I precision approach operations is operational;
- d) it is not expected that an internationally accepted GBAS will be available for Category II and III operations in the 2018-2020 timeframe;
- e) ongoing dual-frequency, multi-constellation (DFMC) GNSS developments will enhance performance of GNSS augmentations as well as enable new operational capabilities in the 2025 timeframe;
- f) technical and operational issues associated with GNSS approach, landing and departure operations, such as vulnerabilities due to ionospheric propagation and radio frequency interference, must be addressed in a timely manner; and
- g) issues associated with DFMC must be addressed in a timely manner.

3.5 Multi-modal airborne approach and landing capability considerations To enable this strategy, a multi-modal airborne approach and landing capability is necessary and is expected to be available.

3.6 Other considerations

- a) There is an increasing demand for Category II and /or III operations in some areas;
- b) GNSS can potentially offer unique operational benefits for low-visibility operations, including new procedures, flexible siting requirements and provision of airport surface guidance;
- c) only the three standard systems (ILS, MLS and GNSS with augmentation as required) are considered to play a major role in supporting all weather operations. The use of head-up displays in conjunction with enhanced and/or synthetic vision systems may provide operational benefits;
- d) a consequence of the global strategy is that there will not be a rapid or complete transition from ILS to new systems such as GNSS or MLS. It is therefore essential for the implementation of the strategy that the radio frequency spectrum used by all of these systems be adequately protected;
- e) the potential operational benefits resulting from the introduction of new landing systems may be limited by the constraints of mixed-system aircraft equipage;
- f) APV operations may be conducted using GNSS with augmentation as required or barometric vertical guidance, and GNSS with ABAS lateral guidance;
- g) APV operations provide enhanced safety and generally lower operational minima as compared to non-precision approaches;

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Strategy for introduction and application of non-visual aids to approach and landing	Attachment B	Page: 3

- h) adequate redundancy should be provided when terrestrial navigation aids are withdrawn; and
- i) rationalization should be part of a national or regional strategy on terrestrial navigation aids; guidance is provided in Attachment H.

4. Strategy

Based on the considerations above, the need to consult aircraft operators, airport operators and international organizations, and to ensure safety, efficiency and cost-effectiveness of the proposed solutions, the global strategy is to:

- a) continue ILS operations to the highest level of service as long as operationally acceptable and economically beneficial;
- b) Continue MLS operations where operationally required and economically beneficial;
- c) implement GNSS with augmentation (i.e. ABAS, SBAS, GBAS) as required for APV and precision approach operations where operationally required and economically beneficial;
- d) promote the continuing development and use of a multi-modal airborne approach and landing capability;
- e) promote the use of APV operations, particularly those using GNSS vertical guidance, to enhance safety and accessibility; and
- f) enable each region to develop an implementation strategy for these systems in line with this global strategy.

Table C-2 (Reserved) Integrity and continuity of service Objectives

3. Material concerning VOR/DVOR

3.1 Guidance relating to VOR/DVOR equivalent isotropically radiated power (EIRP) and coverage

Note - Unless specifically mentioned, all guidance material provided below applies to VOR and DVOR signals.

3.1.1 The field strength specified at Chapter 3, 3.3.4.2, is based on the following consideration:

Airborne receiver sensitivity	-117 dBW
Transmission line loss, mismatch loss, antenna polar pattern variation with respect to an isotropic antenna	+7 dB
Power required at antenna	-110 dBW

The power required of minus 110 dBW is obtained at 118 MHz with a power density of minus 107 dBW/m²; minus 107 dBW/m² is equivalent to 90 microvolts per metre, i.e. plus 39 dB referenced to 1 microvolt per metre.

Note.— The power density for the case of an isotropic antenna may be computed in the following manner:

$$P_d = P_a - 10 \log \frac{\lambda^2}{4\pi}$$

where

P_d = power density in dBW/m²;

P_a = power at receiving point in dBW;

λ = wavelength in metres.

3.1.2 The necessary EIRP to achieve a field strength of 90 microvolts per meter (minus 107 dBW/m²) is given in Figure C-13. The field strength is directly proportional to the antenna elevation pattern. The actual radiation patterns of the antennas depend on a number of factors such as height of the antenna phase center above ground level (AGL), surface roughness, terrain form and conductivity of ground and counterpoise. However, to account for lowest EIRP in notches between the lobes of the real elevation antenna pattern, a conservative value has been provided. Whenever more precise system data are available, a more precise estimation of range is permissible. Further guidance may be found in the *Handbook on Radio Frequency Spectrum Requirements for Civil Aviation including statement of approved ICAO policies* (ICAO Doc 9718).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 6

3.2 Guidance in respect of siting of VOR

3.2.1 VOR is susceptible to multipath interference from surrounding terrain, buildings, trees and power lines. The effect of this should therefore be considered when selecting a site for a new facility, and when considering the acceptability of proposed developments in the vicinity of established sites. Doppler VOR is more resistant to multipath interference than conventional VOR and may be used to provide acceptable performance on more challenging multipath sites.

Note – Guidance on siting of VOR is given in documents EUROCAE ED-52 (including Amendment No. 1), United States Federal Aviation Administration Order 6820.10 and ICAO EUR DOC 015 (First Edition).

3.2.2 The impact of wind farm developments on VOR is an increasing problem due to the growth of interest in alternative energy sources. The impact of wind farms on VOR is difficult to assess for several reasons, including:

- a) the cumulative effect of a group of turbines may be unacceptable even though the effect of each of the turbines may be acceptable individually;
- b) worst-case errors may be experienced when the turbine blades are stationary (due to either high or low wind speeds). The actual error is a function of the orientation of the turbine and position of the turbine blades when stationary;
- c) worst-case errors are likely to be experienced at the limit of coverage and at low elevation angles; and
- d) it is unlikely that the worst-case errors can be confirmed by flight inspections due to the factors listed above.

3.2.3 Computer simulations can be used to assess the effect of wind farms on VOR using worst-case assumptions, as outlined above.

3.3 [Reserved]

3.4 Criteria for geographical separation of VOR type facilities

3.4.1 In using the figures listed in Table C-3, it must be noted that these are derived from the agreed formulae in respect of specific altitudes. In application of the figures, regional meetings would only afford protection to the extent of the operationally required altitude and distance and, by use of the formulae, criteria can be calculated for any distance or altitude.

Figure C-13. Necessary EIRP to achieve a field strength of 90 microvolts per metre (-107 dBW/m^2) as a function of height above and distance from the VOR/DVOR

Note 1 - The curves are based on the IF-77 propagation model with a 4/3 Earth radius which has been confirmed by measurements.

Note 2 - The guidance provided assumes that the VOR/DVOR counterpoise height above ground level (AGL) that defines the antenna pattern is at 3 m (10 ft) AGL over flat terrain. Terrain shielding will reduce the achievable range.

Note 3 - The transmitted power required to achieve an EIRP value as shown depends upon transmitting antenna gain and cable losses. As an example, an EIRP of 25 dBW can be achieved by a VOR with an output power of 100 W, a cable loss of 1 dB and an antenna gain of 6 dBi.

3.4.2 The figures listed are calculated on the assumption that the effective adjacent channel rejection of the airborne receiver is better than 60 dB down at the next assignable channel.

3.4.3 The calculations are based on the assumption that the protection against interference afforded to the wanted signal from the unwanted signal is 20 dB, corresponding to a bearing error of less than 1 degree due to the unwanted signal.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 8

3.4.4 It is recognized that, in the case of adjacent channel operation, there is a small region in the vicinity of a VOR facility, in which interference may be caused to an aircraft using another VOR facility. However, the width of this region is so small that the duration of the interference would be negligible and, in any case, it is probable that the aircraft would change its usage from one facility to the other.

3.4.5 The agreed formulae for calculating the geographical separations are as follows (nautical miles may be substituted for kilometers):

A — *minimum geographical separation (co-channel):*

$$\text{either } 2 D_1 + \frac{20 - K}{S} \text{ km}$$

$$\text{where } D_1 > D_2 + \frac{K}{S}$$

$$\text{or } 2 D_2 + \frac{20 + K}{S} \text{ km}$$

$$\text{where } D_1 < D_2 + \frac{K}{S}$$

B — *geographical separation (adjacent channel):*

collocation case

$$< \frac{40 - K}{S}$$

non-collocated case

$$> 2 D_1 - \frac{40 + K}{S} \text{ km}$$

$$\text{where } D_1 > D_2 + \frac{K}{S}$$

$$\text{or } 2 D_2 - \frac{40 - K}{S} \text{ km}$$

$$\text{where } D_1 < D_2 + \frac{K}{S}$$

C — *geographical separation (adjacent channel)*

(receivers designed for 100 kHz channel spacing in a 50 kHz channel spacing environment)

If receivers having an effective adjacent channel rejection of no better than 26 dB are used (e.g. a 100 kHz receiver used in a 50 kHz environment), a figure of 6 should be substituted for the figure of 40 in the above adjacent channel formulae. In this instance, the geographical collocation formula should not be used as the protection afforded may be marginal.

This lead to the following formula

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

$$> 2D_1 + \frac{6+K}{S} \text{ km}$$

$$\text{where } D_1 > D_2 + \frac{K}{S}$$

$$\text{or } 2D_2 - \frac{6-K}{S} \text{ km}$$

$$\text{where } D_1 < D_2 + \frac{K}{S}$$

Table C-3. Values of geographical separation distances for co-channel operation

Altitude m (ft)	S dB/km (NM)	VOR facilities of equal effective radiated power		VOR facilities which differ in effective radiated power by 6 dB				VOR facilities which differ in effective radiated power by 12 dB			
		Minimum geographical separation between facilities		Minimum geographical separation between facilities				Minimum geographical separation between facilities

18 000 (60 000)	0.09 (0.17)	0	219 (118)	6	65 (35)	154 (83)	284 (153)	12	130 (70)	87 (47)	348 (188)

Note.— S, K and the sign of K are defined in 3.4.5.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 10

D_1, D_2 = service distances required of the two facilities (km).

K = the ratio (dB) by which the effective radiated power of the facility providing D_1 coverage exceeds that of the facility providing D_2 coverage.

Note.— If the facility providing D_2 is of higher effective radiated power, then “K” will have a negative value.

S = slope of the curve showing field strength against distance for constant altitude (dB/km).

3.4.6 The figures listed in Table C-3 are based on providing an environment within which the airborne receivers can operate correctly.

3.4.6.1 In order to protect VOR receivers designed for 50 kHz channel spacing, minimum separations are chosen in order to provide the following minimum signal ratios within the service volume:

the desired signal exceeds an undesired co-channel signal by 20 dB or more;

- a) an undesired signal, 50 kHz removed from the desired signal, exceeds the desired signal by up to 34 dB;
- b) an undesired signal, 100 kHz removed from the desired signal, exceeds the desired signal by up to 46 dB;
- c) an undesired signal, 150 kHz or further removed from the desired signal, exceeds the desired signal by up to 50 dB.

3.4.6.2 In order to protect VOR receivers designed for 100 kHz channel spacing, minimum separations are chosen in order to provide the following minimum signal ratios within the service volume:

1. the desired signal exceeds an undesired co-channel signal by 20 dB or more;
2. an undesired signal, 50 kHz removed from the desired signal, exceeds the desired signal by up to 7 dB;
3. an undesired signal, 100 kHz removed from the desired signal, exceeds the desired signal by up to 46 dB;
4. an undesired signal, 150 kHz or further removed from the desired signal, exceeds the desired signal by up to 50 dB.

3.4.7 Use of the figures given in 3.4.6 or other figures appropriate to other service distances and altitudes implies recognition of the basic assumptions made in this substitution of an approximate method of calculating separation, and the application of the figures will only be correct within the limitations set by those assumptions. The assumptions include that the change of field strength with distance (Factor “S”) at various altitudes of reception is only valid for angles of elevation at the VOR of up to about 5 degrees, but above the radio line of sight. If more precise determination of separation distances is required in areas of frequency congestion, this may be determined for each facility from appropriate propagation curves.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 11

3.4.8 The deployment of 50 kHz channel spacing requires conformity with Chapter 3, 3.3.2.2 and 3.3.5.7 and BCAR 10, Volume V, Chapter 4, 4.2.4. Where, due to special circumstances it is essential during the initial conversion period from 100 kHz channel spacing to 50 kHz channel spacing to take account of nearby VOR facilities that do not conform with Chapter 3, 3.3.2.2 and 3.3.5.7 and BCAR 10, Volume V, Chapter 4, 4.2.4, greater geographical separation between these and the new facilities utilizing 50 kHz channel spacing will be required to ensure a bearing error of less than one degree due to the unwanted signal. On the assumption that the sideband levels of the 9 960 Hz harmonic of the radiated signal of such facilities do not exceed the following levels:

9 960 Hz	0 dB reference
2nd harmonic	-20 dB
3rd harmonic	-30 dB
4th harmonic and above	-40 dB

the separation formulae at 3.4.5 should be applied as follows:

- a) where only receivers designed for 50 kHz channel spacing need to be protected, the value of 40 should be replaced by 20 in the formula at B — non-collocated case;
- b) where it is necessary to protect receivers designed for 100 kHz channel spacing, the co-channel formula at A — co-channel case, should be applied for the range of altitudes for which protection is required.

3.4.9 When DME/N facilities and VOR facilities are intended to operate in association with each other, as outlined in Chapter 3, 3.5.3.3.4, and have a common service volume, both the co-channel and adjacent channel geographical separation distances required by the DME are satisfied by the separation distances of the VOR as computed in this section, provided the distance between VOR and DME does not exceed 600 m (2 000 ft). A potential interference situation may also occur with the implementation of DME “Y” channels since interference between two DME ground stations spaced 63 MHz apart could occur when transmitting and receiving on the same frequency (e.g. transmissions from channel 17 Y could interfere with reception on channels 80 X and 80 Y). To obviate any ground receiver desensitization due to this interference, a minimum ground separation distance of 18.5 km (10 NM) between facilities is necessary.

3.5 Criteria for geographical separation of VOR/ILS facilities

3.5.1 In using the figures of 3.5.3.1 and 3.5.3.2, it is to be borne in mind that the following assumptions have been made:

- a) that the localizer receiver characteristic is as shown in 2.6.2, and the VOR receiver characteristic as shown in 3.4.2;
- b) that the protection ratio for the ILS system and the VOR system is 20 dB as in 2.6.4 and 3.4.3, respectively;
- c) that the protection point for ILS is at a service distance of 46.25 km (25 NM) measured along the line of use, and at an altitude of 1 900 m (6 250 ft).

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 12

Note -With the advent of highly directional ILS localizer antenna arrays, the most critical protection point will not be along the extended runway center line. Directive antennas result in critical protection points at maximum distance, either plus or minus 10 degrees or plus or minus 35 degrees off the runway center line. Protection of these points should be examined during the frequency assignment process.

3.5.2 Although international VOR and ILS facilities will not appear on the same frequency, it may occur that an international VOR facility may share temporarily the same frequency as, and on a comparable basis with, a national ILS facility. For this reason, guidance is given as to the geographical separation required not only for a VOR and an ILS facility separated by 50 kHz or 100 kHz, but also for co-channel usage.

3.5.3 Because of the differing characteristics of use of the two equipments, the criteria for minimum geographical separation of VOR/ILS to avoid harmful interference are stated separately for each facility where relevant.

3.5.3.1 Co-channel case

- a) Protection of the ILS system requires that a VOR having an ERP of 17 dBW (50 W) be at least 148 km (80 NM) from the ILS protection point.
- b) On the assumption that a VOR having an ERP of 17 dBW (50 W) is to be protected to a service distance of 46.25 km (25 NM) and an altitude of 3 000 m (10 000 ft), protection of the VOR system requires that the ILS be at least 148 km (80 NM) from the VOR.
- c) If protection of the VOR is required to, say, 92.5 km (50 NM) and 6 000 m (20 000 ft), the ILS is to be at least 250 km (135 NM) from the VOR.

3.5.3.2 Adjacent channel case. Protection of the VOR system is effectively obtained without geographical separation of the facilities. However, in the case of:

- a) a localizer receiver designed for 100 kHz channel spacing and used in an area where navaid assignments are spaced at 100 kHz, the protection of the ILS system requires that a VOR having an ERP of 17 dBW (50 W) be at least 9.3 km (5 NM) from the ILS protection point;
- b) a localizer receiver designed for 100 kHz channel spacing and used in an area where assignments are spaced at 50 kHz, the protection of the ILS system requires that a VOR having an ERP of 17 dBW (50 W) be at least 79.6 km (43 NM) from the ILS protection point.

3.5.4 Use of the figures given in 3.5.3 or other figures appropriate to other service distances and altitudes implies recognition of the basic assumptions made in this substitution of an approximate method of calculating separation, and the application of the figures will only be correct within the limitations set by those assumptions. If more precise determination of separation distances is required in areas of frequency congestion, this may be determined for each facility from appropriate propagation curves.

3.5.5 Protection of the ILS system from VOR interference is necessary where a VOR facility is located near an ILS approach path. In such circumstances, to avoid disturbance of the ILS receiver output due to possible cross modulation effects, suitable frequency separation between the ILS and VOR channel frequencies should be used. The frequency separation will be dependent upon the ratio of the VOR and ILS field densities, and the characteristics of the airborne installation.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 13

3.6 Receiving function

3.6.1 Sensitivity. After due allowance has been made for aircraft feeder mismatch, attenuation loss and antenna polar diagram variation, the sensitivity of the receiving function should be such as to provide on a high percentage of occasions the accuracy of output specified in 3.6.2, with a signal having a field strength of 90 microvolts per meter or minus 107 dBW/m².

3.6.2 Accuracy. The error contribution of the airborne installation should not exceed plus or minus 3 degrees with a 95 per cent probability.

Note 1 - The assessment of the error contribution of the receiver will need to take account of:

1. *The tolerance of the modulation components of the ground VOR facility as defined in Chapter 3, 3.3.5;*
2. *variation in signal level and carrier frequency of the ground VOR facility;*
3. *the effects of unwanted VOR and ILS signals.*

Note 2 - The airborne VOR installation is not considered to include any special elements which may be provided for the processing of VOR information in the aircraft and which may introduce errors of their own (e.g. radio magnetic indicator (RMI)).

3.6.3 Flag alarm operation. Ideally, the flag alarm should warn a pilot of any unacceptable malfunctioning conditions which might arise within either the ground or airborne equipments. The extent to which such an ideal might be satisfied is specified below.

3.6.3.1 The flag alarm movement is actuated by the sum of two currents which are derived from the 30 Hz and 9 960 Hz elements of the VOR bearing component signal and, therefore, the removal of these elements from the radiated carrier results in the appearance of the flags. Since the VOR ground monitor interrupts the bearing components when any unacceptable condition prevails on the ground, there will be an immediate indication within an aircraft when the system is unusable.

3.6.3.2 The flag alarm movement current is also dependent upon the AGC characteristics of the airborne equipment and any subsequent gain following the receiver's second detector. Thus, if with a correctly adjusted airborne receiver the flag is just out of view when receiving a VOR signal conforming to the modulation characteristics specified in Chapter 3, 3.3.5, the flags will again become visible in the event of a decrease in the receiver's overall gain characteristics.

Note - Certain types of receivers employ warning indications other than mechanical flags to perform the functions described here.

3.6.4 VOR receiver susceptibility to VOR and localizer signals

3.6.4.1 The receiver design should provide correct operation in the following environment:

- a) the desired signal exceeds an undesired co-channel signal by 20 dB or more;

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 14

- b) an undesired signal, 50 kHz removed from the desired signal, exceeds the desired signal by up to 34 dB (during bench testing of the receiver, in this first adjacent channel case, the undesired signal is varied over the frequency range of the combined ground station (plus or minus 9 kHz) and receiver frequency tolerance);
- c) an undesired signal, 100 kHz removed from the desired signal, exceeds the desired signal by up to 46 dB;
- d) an undesired signal, 150 kHz or further removed from the desired signal, exceeds the desired signal by up to 50 dB.

Note 1 - It is recognized that not all receivers currently meet requirement b); however, all future equipments are designed to meet this requirement.

3.6.5 Immunity performance of VOR receiving systems to interference from VHF FM broadcast signals

3.6.5.1 With reference to Chapter 3, 3.3.8, the immunity performance defined therein must be measured against an agreed measure of degradation of the receiving system's normal performance, and in the presence of, and under standard conditions for the input wanted signal. This is necessary to ensure that the testing of receiving equipment on the bench can be performed to a repeatable set of conditions and results and to facilitate their subsequent approval. Additional information can be found in ITU Recommendation ITU-R SM.1140, Test procedures for measuring aeronautical receiver characteristics used for determining compatibility between the sound-broadcasting service in the band of about 87–108 MHz and the aeronautical services in the band 108–118 MHz.

Note - Receiver test procedures are also given in the VOR receiver MOPS (RTCA DO-196, and EUROCAE ED-22B).

3.6.5.2 Commonly agreed formulae should be used to assess potential incompatibilities to receivers meeting the general interference immunity criteria specified in Chapter 3, 3.3.8. The formulae provide clarification of immunity interference performance of spurious emission (type A1) interference, out-of-band channel (type A2) interference, two-signal and three-signal third order (type B1) interference, and overload/desensitization (type B2) interference. Additional information can be found in ITU Recommendation ITU-R IS.1009-1, *Compatibility between the sound-broadcasting service in the band of about 87–108 MHz and the aeronautical services in the band 108–137 MHz.*

3.7 VOR system accuracy

Note - Guidance material on the determination of VOR system performance values is also contained in BCAR 11, Attachment A.

3.7.1 Purpose. The following guidance material is intended to assist in the use of VOR systems. It is not intended to represent lateral separation standards or minimum obstacle clearances, although it may of course provide a starting point in their determination. The setting of separation standards or minimum obstacle clearances will necessarily take account of many factors not covered by the following material.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 15

3.7.1.1 There is, however, a need to indicate a system use accuracy figure for the guidance for planning VOR systems.

3.7.2 Explanation of terms. The following terms are used with the meanings indicated:

- a) VOR radial signal error. The difference between the nominal magnetic bearing to a point of measurement from the VOR ground station and the bearing indicated by the VOR signal at that same point. The VOR radial signal error is made up of certain stable elements, such as course displacement error and most site and terrain effect errors, and certain random variable errors. The VOR radial signal error is associated with the ground station only and excludes other error factors, such as airborne equipment errors and pilotage element.
- b) VOR radial variability error. That part of the VOR radial signal error which can be expected to vary about the essentially constant remainder. The radial variability error is the sum of the variable errors.
- c) VOR radial displacement error. That part of the VOR radial signal error which is stable and may be considered as fixed for long periods of time.
- d) VOR airborne equipment error. That error attributable to the inability of the equipment in the aircraft to translate correctly the bearing information contained in the radial signal. This error includes the contributions of the airborne receiver and the instrumentation used to present the information to the pilot.
- e) VOR aggregate error. The difference between the magnetic bearing to a point of measurement from the VOR ground station and the bearing indicated by airborne VOR equipment of stated accuracy. More simply put, this is the error in the information presented to the pilot, taking into account not only the ground station and propagation path errors, but also the error contributed by the airborne VOR receiver and its instrumentation. The entire VOR radial signal error, both fixed and variable, is used.
- f) VOR pilotage element. The error in the use of VOR navigation attributable to the fact that the pilot cannot or does not keep the aircraft precisely at the centre of the VOR radial or bearing indicated by the equipment.
- g) VOR system use error. The square root of the sum of the squares (RSS) of VOR aggregate error and the pilotage element. This combination may be used to determine the probability of an aircraft remaining within specified limits when using VOR.

3.7.3 Calculation of VOR system use accuracy

3.7.3.1 The VOR system use accuracy is derived by considering the following error elements:

- a) VOR radial signal error (Eg). This element consists of the radial displacement error and the radial variability error. It is determined by considering such factors as fixed radial displacement, monitoring, polarization effects, terrain effects and environment changes.
- b) VOR airborne equipment error (Ea). This element embraces all factors in the airborne VOR system which introduces errors (errors resulting from the use of compass information in some VOR displays are not included).

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 16

- c) VOR pilotage element (Ep). The value taken for this element is that used in PANS-OPS (ICAO Doc 8168) for pilot tolerance.

Note - A measurement error also exists, but in a generalized discussion of errors may be considered to be absorbed in the other error values.

3.7.3.2 Since the errors in a), b), and c), when considered on a system basis (not any one radial) are independent variables, they may be combined on a root-sum-square method (RSS) when the same probability level is given to each element. For the purpose of this material, each element is considered to have a 95 per cent probability.

Therefore, the following formulae are derived:

$$\text{VOR aggregate error} = \sqrt{E_g^2 + E_a^2}$$

$$\text{VOR system use error} = \sqrt{E_g^2 + E_a^2 + E_p^2}$$

3.7.3.3 The following examples will derive only the VOR system use error but calculations can also be made to determine VOR aggregate error, if desired. By use of these formulae, the impact on the system of improvement or degradation of one of more error elements can be assessed.

Note - All figures for VOR radial signal error are related to radials for which no restrictions are published.

3.7.3.4 Subject to the qualifications indicated in 3.7.1, it is considered that a VOR system use accuracy of plus or minus 5 degrees on a 95 per cent probability basis is a suitable figure for use for planning the application of the VOR system (see, however, 3.7.3.5). This figure corresponds to the following component errors:

VOR radial signal error:

plus or minus 3° (95 per cent probability), a value readily achieved in practice.

VOR airborne equipment error:

plus or minus 3° (95 per cent probability), system characteristics value (see 3.6.2).

VOR pilotage element:

plus or minus 2.5° (95 per cent probability), in accordance with PANS-OPS (see also 3.7.3.8).

3.7.3.5 While the figure of plus or minus 5 degrees on a 95 per cent probability basis is a useful figure based on broad practical experience, it must be noted that this figure may be achieved only if the error elements which make it up remain within certain tolerances. It is clear that, if the errors attributable to the VOR system elements are larger than the amounts noted, the resulting VOR system use error will also be larger. Conversely, where any or all of the VOR system error elements are smaller than those used in the above computation, the resulting VOR system use error will also be smaller.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 17

3.7.3.6 The following examples, also derived from practical experience, provide additional planning guidance :

A.— VOR radial signal error:

plus or minus 3.5° (95 per cent probability), as the total ground system error.

VOR airborne equipment error:

plus or minus 4.2° (95 per cent probability), as the minimum performance figure for some classes of operations.

VOR pilotage element:

plus or minus 2.5° (95 per cent probability), in accordance with PANS-OPS (see also 3.7.3.8).

Calculated VOR system use accuracy:

plus or minus 6° (95 per cent probability).

B. — VOR radial signal error:

plus or minus 1.7° (95 per cent probability), based on extensive flight measurements conducted in one State on a large number of VORs.

VOR airborne equipment error:

plus or minus 2.7° (95 per cent probability), achieved in many airline operations.

VOR pilotage element:

plus or minus 2.5° (95 per cent probability), in accordance with PANS-OPS (see also 3.7.3.8).

Calculated VOR system use accuracy:

plus or minus 4° (95 per cent probability).

3.7.3.7 More realistic application of the VOR system may be achieved by assessing the errors as they actually exist in particular circumstances, rather than by using all-embracing generalizations which may give unduly optimistic or pessimistic results. In individual applications, it may be possible to utilize a system use accuracy value less than plus or minus 5 degrees if one or more of the error elements are smaller than the values used to compute the plus or minus 5 degrees. Conversely, a system use accuracy value greater than plus or minus 5 degrees will be necessary where it is known that radials are of poor quality or significant site errors exist, or for other reasons. However, in addition to this advice a warning is also essential regarding the use of lower values of individual elements in the system (for example, the radial signal error) on the assumption that an overall improvement in system accuracy will occur. There is considerable evidence that this may not be the case in some circumstances and that lower system accuracy values should not be applied without other confirmation (e.g. by radar observation) that an actual improvement in overall performance is being achieved.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 18

3.7.3.8 It is to be noted that in angular systems such as the VOR, the pilotage element error, expressed in angular terms, will be greater as the aircraft nears the point source. Thus, while ground system and airborne error contributions, expressed in angular terms, are for all practical purposes constant at all ranges, it is necessary when considering the overall system use accuracy figures to take into account the larger pilotage element error occurring when the aircraft is near the VOR. However, these larger pilotage element errors do not result in large lateral deviations from course when near the facility.

3.8 Changeover points for VORs

Guidance on the establishment of changeover points on ATS routes defined by VORs is contained in BCAR-11, Attachment A.

6. Material concerning NDB

6.1 Guidance material on NDB field strength requirements in latitudes between 30°N and 30°S

6.1.1 In order to obtain a satisfactory service within the rated coverage of an NDB located in latitudes between 30°N and 30°S, a minimum value of field strength of 120 microvolts per meter would be required, except where practical experience in the operation of NDBs over several years has revealed that a minimum field strength of 70 microvolts per meter would be adequate to meet all the operational needs. In some specific areas, field strength values considerably in excess of 120 microvolts per meter would be required. Such areas are:

- a) Indonesia and Papua New Guinea, Myanmar, Malay Peninsula, Thailand, Lao People's Democratic Republic, Democratic Kampuchea, Viet Nam and Northern Australia;
- b) Caribbean and northern parts of South America;
- c) Central and South Central Africa.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 19

6.1.2 The field strength of 120 microvolts per meter is based upon practical experience to date and is a compromise between what is technically desirable and what it is economically possible to provide.

6.2 Guidance material on meaning and application of rated and effective coverage

6.2.1 Rated coverage

6.2.1.1 The rated coverage as defined in Chapter 3, 3.4.1, is a means of designating actual NDB performance, in a measurable way, which is dependent on the frequency, the radiated power, and the conductivity of the path between the NDB and a point on the boundary where the minimum value of field strength is specified.

6.2.1.2 The rated coverage has been found to be a useful means of facilitating regional planning and, in some instances, may be related to effective coverage.

6.2.1.3 The application of rated coverage to frequency planning is governed by the following criteria:

6.2.1.3.1 Frequencies should be deployed having regard to the rated coverage of the NDBs concerned, so that the ratio of the signal strength of any NDB at the boundary of its rated coverage to the total field strength due to co-channel stations and adjacent channel stations (with an appropriate allowance for the selectivity characteristics of a typical airborne receiver) is not less than 15 dB by day.

6.2.1.3.2 The figures set forth in Attachment B to Volume V of BCAR 10 should be applied, as appropriate, in determining the allowance to be made for the attenuation of adjacent channel signals.

6.2.1.4 It follows from the application of rated coverage to frequency deployment planning that, unless otherwise specified, protection against harmful interference can only be ensured within the rated coverage of an NDB and, then, only if the radiated power of the NDBs is adjusted to provide within reasonably close limits the field strength required at the limit of the rated coverage. In areas where the density of NDBs is high, any NDB providing a signal at the limit of its rated coverage materially in excess of that agreed in the region concerned will give rise, in general, to harmful interference within the rated coverages of co-channel or adjacent channel NDBs in the area concerned, and will limit the number of NDBs which can be installed in the region within the available spectrum. It is important, therefore, that increases in radiated power beyond that necessary to provide the rated coverage, particularly at night when sky wave propagation may give rise to interference over long distances, should not be made without coordination with the authorities of the other stations likely to be affected (see Chapter 3, 3.4.3).

6.2.1.5 Frequency planning is considerably facilitated if a common value of minimum field strength within the desired coverage is used.

6.2.1.6 Extensive experience has shown that in relatively low noise level areas, such as Europe, the figure of 70 microvolts per meter is satisfactory.

6.2.1.6.1 Experience has also shown that the figure of 120 microvolts per meter is generally satisfactory for higher noise level areas but will be inadequate in areas of very high noise. In such areas, the information given in 6.3 may be used for general guidance.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 20

6.2.2 Relationship to effective coverage

6.2.2.1 Rated coverage may have a close correlation to effective coverage under the following conditions:

- a) when the minimum field strength within the rated coverage is such that, for most of the time, it exceeds the field strength due to atmospheric and other noise sufficiently to ensure that the latter will not distort the information presented in the aircraft to the extent that it is unusable;
- b) when the ratio of the strength of the wanted signal to that of interfering signals exceeds the minimum required value at all points within the coverage, in order to ensure that interfering signals will also not distort the information presented in the aircraft to the extent that it is unusable.

6.2.2.2 Since, normally, the lowest signal within the coverage will occur at its boundary, these conditions imply that at the boundary the field strength should be such that its ratio to atmospheric noise levels would ensure usable indications in the aircraft for most of the time and that, in respect of the boundary value, overall planning should ensure that the ratio of its value to that of interfering signals exceeds the required value for most of the time.

6.2.2.3 Although the value of 70 microvolts per meter used for frequency deployment has been found successful in Europe (i.e. north of 30° latitude) in giving coverage values which closely approximate to effective coverage most of the time, experience is too limited to prove the suitability of the 120 microvolts per meter value for general application in areas of high noise. It is to be expected that rated coverages in high noise based on a boundary value of 120 microvolts per meter will, on many occasions, be substantially greater than the effective coverage achieved. In such areas, in order to secure a better correlation between rated coverage and an average of the achieved effective coverage, it may be advisable to choose a boundary value based more closely on the proportionality of noise in that area to the noise in areas where a boundary value has been satisfactorily established (e.g. Europe), or to determine an appropriate value from a statistical examination of achieved effective coverages in respect of an NDB in the area of known performance.

6.2.2.4 It is important to appreciate, however, that minimum values of field strength based on a simple comparison of noise levels in different areas may be insufficient, because factors such as the frequency of occurrence of noise, its character and effect on the airborne receiver and the nature of the air operation involved may all modify ratios determined in this way.

6.2.2.5 Values of diurnal and seasonal noise in various parts of the world have been published in Report 322 of the former CCIR of the ITU.

6.2.2.5.1 Correlation of these values to actual local conditions and the derivation of required signal-to-noise ratios for effective operational use of ADF equipment is not yet fully established.

6.2.3 Effective coverage

6.2.3.1 Effective coverage as defined in Chapter 3, 3.4.1, is the area surrounding an NDB, within which useful information to the operator concerned can be obtained at a particular time. It is, therefore, a measure of NDB performance under prevailing conditions.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 21

6.2.3.2 The effective coverage is limited by the ratio of the strength of the steady (non-fading) signal received from the NDB to the total noise intercepted by the ADF receiver. When this ratio falls below a limiting value, useful bearings cannot be obtained. It should also be noted that the effective coverage of an NDB may in some cases be limited to the range of the usable identification signal.

6.2.3.3 The strength of signal received from the NDB is governed by:

- a) the power supplied to the antenna of the NDB;
- b) the radiation efficiency of the antenna, which varies according to the height of the antenna and other characteristics of the radiating system;
- c) the conductivity of the path between the NDB and the receiver, which may vary considerably as between one site and another, and is always less over land than over seawater;
- d) the operating radio frequency.

6.2.3.4 The noise admitted by the receiver depends on:

- a) the bandwidth of the receiver;
- b) the level of atmospheric noise, which varies according to the geographical area concerned, with the time of day and the season of the year, and which may reach very high levels during local thunderstorms;
- c) the level of the interference produced by other radio emissions on the same or on adjacent frequencies, which is governed to a large extent by the NDB density in the area concerned and the effectiveness of regional planning;
- d) the level of noise due to electrical noise in the aircraft or to industrial noise (generated by electric motors, etc.), when the coverage of the NDB extends over industrial areas.

6.2.3.4.1 It has to be noted that the effect of noise depends on characteristics of the ADF receiver and the associated equipment, and also on the nature of the noise (e.g. steady noise, impulsive noise).

6.2.3.5 A further factor which limits the effective coverage of an NDB is present at night when interaction occurs between components of the signal which are propagated respectively in the horizontal plane (ground wave propagation) and by reflection from the ionosphere (sky wave propagation). When there is interaction between these components, which arrive at the ADF receiver with a difference of phase, bearing errors are introduced (night effect).

6.2.3.6 It will thus be seen that the effective coverage of an NDB depends on so many factors, some of which are variable, that it is impossible to specify the effective coverage of an NDB in any simple manner. The effective coverage of any NDB, in fact, varies according to the time of day and the season of the year.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 22

6.2.3.6.1 Hence any attempt to specify an effective coverage, which would be obtainable at any time throughout the day or throughout the year, would result either in a figure for coverage which would be so small (since this would be the coverage obtained under the worst conditions of atmospheric noise, etc.) as to give quite a misleading picture of the effectiveness of the NDB, or would involve such high power and costly antenna systems (to provide the required coverage under the worst conditions), that the installation of such an NDB would usually be precluded by considerations of initial and operating costs. No specific formula can be given in determining what rated coverage would be equivalent to a desired effective coverage and the relation must be assessed regionally.

6.2.3.7 Those concerned with the operational aspects of NDB coverage will normally consider requirements in terms of a desired operational coverage and, in regional planning, it will usually be necessary to interpret such requirements in terms of a rated coverage from which may be derived the essential characteristics of the NDB required and which will also define the area to be protected against harmful interference. No specific formula can be given in determining what rated coverage would be equivalent to a desired operational coverage and the relation must be assessed regionally.

6.2.3.8 Some States have recorded data on NDBs and their effective coverage; and collection of similar information would be a practical way of obtaining an assessment of effective coverage in terms of rated coverage of facilities in a given area. This information would also be useful for future regional planning. In order to reduce the number of factors involved in assessing effective coverage, it would be desirable to establish criteria for determining the limit of useful coverage in terms of the reaction of the bearing indicator. The data referred to previously, together with measurements of actual field strength within the coverage of the NDB, would also permit determination of the effectiveness of existing installations and provide a guide to improvements that may be necessary to achieve a desired effective coverage.

6.3 Coverage of NDBs

6.3.1 Introduction

6.3.1.1 The following studies have been based on the latest propagation and noise data available to the ITU. They are included in this Attachment as general guidance in respect of NDB planning. Attention is called particularly to the assumptions made.

6.3.1.2 When applying the material, the validity of the assumptions in respect of the particular conditions under consideration should be carefully examined and, in particular, it should be noted that the assumed signal-to-noise ratios require considerable further study before they can be accepted as representative of the ratios limiting useful reception.

6.3.2 Assumptions

1. Operating frequency — 300 kHz.

Reference is made, however, where appropriate, to frequencies of 200 kHz and 400 kHz.

2. a) Average soil conductivity: ($\sigma = 10^{-13}$ e.m.u.)
b) Average seawater conductivity: ($\sigma = 4.10^{-11}$ e.m.u.)

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 23

3. The level of atmospheric noise (RMS) which is likely to prevail: 1) by day, 2) by night, over land masses, within the belts of latitude mentioned. [The values of expected noise have been derived from Recommendation ITU-R P.372-6 and have been taken as the average noise by day and by night during equinox periods, i.e. the values which are likely to be exceeded 20–25 per cent of the year.]

4. Input powers to the antenna of the NDB of:

- a) kW
- b) 1 kW
- c) 500 W
- d) 100 W
- e) 50 W
- f) 10 W

5. The following average values of radiation efficiencies of antennas, i.e. the ratio of:

$$\left[\frac{\text{Radiated power}}{\text{Input power to antenna}} \right]$$

	<i>Input power to antenna</i>	<i>Radiation efficiency of antenna</i>
a)	5 kW	20% (−7 dB)
b)	5 kW	10% (−10 dB)
c)	1 kW	8% (−11 dB)
d)	500 W	5% (−13 dB)
e)	100 W	3% (−15 dB)
f)	50 W	2% (−17 dB)
g)	10 W	1% (−20 dB)
h)	10 W	0.3% (−25 dB)

i. The figure for a) is included because it is possible to realize this efficiency by the use of a more elaborate antenna system than is usually employed.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

ii. The figure for h) is included because many low power NDBs use very inefficient antennas.

6. An admittance band of the ADF receiver of 6 kHz.

7. Required ratios of signal-(median) to-noise (RMS) of:

a) 15 dB by day;

b) 15 dB by night.

6.3.3 Results of studies

A.— *Minimum field strengths required at the boundary of the rated coverage:*

<i>Latitude</i>	<i>By day for 15 dB S/N ratio</i>	<i>By night for 15 dB S/N ratio</i>
5°N – 5°S	320 μV/m (+50 dB)	900 μV/m (+59 dB)
5° – 15°N&S	85 μV/m (+39 dB)	700 μV/m (+57 dB)
15° – 25°N&S	40 μV/m (+32 dB)	320 μV/m (+50 dB)
25° – 35°N&S	18★ μV/m (+25 dB)	120 μV/m (+42 dB)
>35°N&S	18★ μV/m (+25 dB)	50 μV/m (+35 dB)

A star shown against a figure indicates that a higher value of field strength — probably 2 or 3 times the values shown (plus 6 to plus 10 dB) — may be necessary in the presence of high aircraft noise and/or industrial noise.

B - Coverage of NDBs (expressed in terms of the radius of a circle, in kilometers, with the NDB at the center) which may be expected under the assumptions made:

1) *By day, over land, and for 15 dB S/N ratio at the boundary of the coverage:*

<i>Latitude</i>	<i>Input power to antenna</i>			
	<i>(a) 5 kW</i>	<i>(b) 5 kW</i>	<i>(c) 1 kW</i>	<i>(d) 500 W</i>
5°N – 5°S	320	300	170	120
5° – 15°N&S	510	470	320	250
15° – 25°N&S	>600	600	450	350
25° – 35°N&S	>600★	>600★	600★	500★
>35°N&S	>600★	>600★	>600★	500★

<i>Input power to antenna</i>			
<i>(e)</i>	<i>(f)</i>	<i>(g)</i>	<i>(h)</i>

<i>Latitude</i>	<i>100 W</i>	<i>50 W</i>	<i>10 W</i>	<i>10 W</i>
5°N – 5°S	50	30	10	<10
5° – 15°N&S	150	90	40	10
15° – 25°N&S	220	160	70	45
25° – 35°N&S	330★	250★	130★	80★
>35°N&S	330★	250★	130★	100★

2) By night, over land, and for 15 dB S/N ratio at the boundary of the coverage:

<i>Latitude</i>	<i>Input power to antenna</i>			
	<i>(a)</i> <i>5 kW</i>	<i>(b)</i> <i>5 kW</i>	<i>(c)</i> <i>1 kW</i>	<i>(d)</i> <i>500 W</i>
5°N – 5°S	190	150	85	50
5° – 15°N&S	210	180	110	70
15° – 25°N&S	320	300	170	120
25° – 35°N&S	390	390	280	200
>35°N&S	390	390	390	310

<i>Latitude</i>	<i>Input power to antenna</i>			
	<i>(e)</i> <i>100 W</i>	<i>(f)</i> <i>50 W</i>	<i>(g)</i> <i>10 W</i>	<i>(h)</i> <i>10 W</i>
5°N – 5°S	20	<10	<10	<10
5° – 15°N&S	25	15	<10	<10
15° – 25°N&S	50	30	10	<10
25° – 35°N&S	100	70	25	15
>35°N&S	180	120	50	30

6.3.3.1 In all of the above tables, it has to be noted that:

- the distances are given in kilometers, in accordance with ITU practice;
- the figures in the final columns, with the heading 10 W, are calculated on the assumption that the low power NDB uses a very inefficient antenna (see 6.3.2, assumption 5 h));
- a star shown against a figure indicates that the coverage may be limited by aircraft and industrial noises.

6.3.3.2 It has also to be noted that:

- if a frequency of 200 kHz were used in place of 300 kHz, this would not appreciably affect the coverage of low power short range NDBs, but the coverage of the higher power, longer range beacons (for

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 26

example, those with a range of 150 km or more) would be increased, as compared with those shown in the tables, by about 20 per cent;

- b) if a frequency of 400 kHz were used in place of 300 kHz this would not appreciably affect the coverage of low power short range NDBs, but the coverage of the higher power, longer range beacons (for example, those with a range of 150 km or more) would be decreased, as compared with those shown in the tables, by about 25 per cent;
- c) use of an ADF receiver with a narrower band would, other things being equal, provide wider coverage for the same radiated power of the NDB or, for the same coverage, an improved effective signal-to-noise ratio.

For example, if an admittance band of 1 kHz instead of 6 kHz were used, the coverage might be increased by as much as 30 per cent for the same radiated power or, alternatively, the effective signal-to-noise ratio might be increased by as much as 8dB;

- d) if a sector of the coverage of an NDB is over seawater, a greater coverage may be expected within that sector due to:
 - i. better ground wave propagation over seawater than over land;
 - ii. the noise level, which is highest over land, often drops fairly steeply with increasing distance from the land. It might be assumed, therefore, that the distances shown in the tables could be increased by about 30 per cent by day, and by about 20 per cent by night, when the path is over seawater;
- e) if, however, the beacon is sited on an island remote from land masses (for example, in mid-Pacific or mid-Atlantic, but not in the Caribbean), the coverage of the beacon is likely to be much greater, particularly in tropical latitudes, than is indicated in the tables; and in such cases figures for coverage similar to those shown for latitudes more than 35°N and S may be assumed for all latitudes, due to the much lower level of atmospheric noise which prevails in mid-ocean as compared with that experienced over, or in proximity to, land masses.

6.3.4 Limitation of coverage of a beacon at night due to “night effect”.

- a) The distances, at night, at which the ground wave and sky wave components of the received field are likely to be equal are as follows:

<i>Frequency</i>	<i>Over land</i>	<i>Over sea</i>
200 kHz	500 km	550 km
300 kHz	390 km	520 km
400 kHz	310 km	500 km

- b) The distances, at night, at which the ground wave component of the received field is likely to exceed the sky wave component by 10 dB are as follows:

<i>Frequency</i>	<i>Over land</i>	<i>Over sea</i>	
Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 27

200 kHz	300 km	320 km
300 kHz	230 km	300 km
400 kHz	200 km	280 km

- c) It is, therefore, unlikely that reliable bearings can be obtained, at night, due to interaction of the two components of the received field, at much greater distances than those shown in 6.3.4 b). *These distances are independent of the power of the NDB.*
- d) It has to be noted, moreover, that, while with overland paths of good conductivity, night effect will only be serious at somewhat greater distances than those indicated over paths of poor conductivity, night effect may become pronounced at much shorter ranges. This will also depend to some extent upon the characteristics of the radiation system.

6.4 Considerations affecting operations of NDBs

6.4.1 Depth of modulation

6.4.1.1 In specifying that the depth of modulation should be maintained as near to 95 per cent as is practicable, it must be noted that, at the frequencies used for NDBs, the small antennas generally in use can affect the effective modulation depth of the NDB system due to attenuation of the sidebands.

6.4.1.2 At this order of frequency, the antennas are normally only a small fraction of a wavelength long; they are therefore highly reactive and tend to have a high Q.

6.4.1.3 The effect is illustrated in Figure C-19, which was compiled from measurements made by one State. The modulating frequency in these measurements was 1 020 Hz. If a lower modulating frequency were used, the effect would be less.

6.4.1.4 In order to reduce the attenuation, attempts should be made to reduce the Q of the antenna. This can be done in two ways, by increasing either its capacity or resistance.

6.4.1.5 Inserting additional resistance in an antenna wastes power, whereas increasing the capacity does not. Additionally, the effect of increasing the capacity is to reduce the voltage across the system and hence to reduce the insulation problems.

6.4.1.6 For these reasons, it is considered desirable to increase antenna capacity by the use of a top load as, for example, in the so-called umbrella top capacity.

6.4.2 Earth systems

Frequency planning is done on the assumption that the field strength will be maintained at the correct value. If the earth resistance is high (i.e. an insufficient earth system), not only will the radiation efficiency be low but the power radiated will be sensitive to changes in climatic conditions and other factors affecting the earth loss. In all cases, the earth system needs to be the best possible, taking into account all local circumstances.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

Figure C-19. The effect of antenna Q on the depth of modulation of the radiated signal

6.5 Considerations affecting the choice of the modulating frequency for NON/A2A NDBs

Recognition of the fact that modern narrow band ADF receivers have improved selectivity characteristics requires consideration of the fact that, in so far as attenuation of the audio sidebands by these receivers results in a reduction of the effective depth of modulation of the signal, the distance at which satisfactory identification is obtained is consequently reduced. In such circumstances, it is considered that 400 Hz would provide a better identification service than 1 020 Hz. There is some evidence, however, that under conditions of high atmospheric noise, the higher frequency of 1 020 Hz may provide a more easily readable signal.

7. Material concerning DME

7.1 Guidance material concerning both DME/N and DME/P

7.1.1 System efficiency

7.1.1.1 System efficiency is the combined effect of down-link garble, ground transponder dead time, up-link garble, and interrogator signal processor efficiency. Since each of these efficiency components are statistically independent, they can be computed individually and then combined to yield the system efficiency. The effect of a single component is defined as the percentage ratio of valid replies processed by the interrogator in response to its own interrogations assuming all other components are not present. The system efficiency is then the product of the individual components.

7.1.1.2 In computing system efficiency, the number of missing replies as well as the accuracy of the range measurement made with the received replies should be considered. Missing replies may result from signal interference due to garble or from interrogations being received at the transponder during a dead time period. Replies which contain significant errors large enough to be rejected by the interrogator signal processing also should be treated as missing replies when computing the efficiency component.

7.1.1.3 The interference rate due to garble is dependent upon the channel assignment plan, traffic loading, and the ground transponder and interrogator receiver bandwidths. Because the FA mode has a wider receiver bandwidth than the IA mode, it is more susceptible to interference. These factors were accommodated in the DME/P system definition and normally do not require special consideration by the operating authority.

7.1.2 Down-link garble

Down-link garble occurs when valid interrogations at the ground transponder are interfered with by coincident interrogations from other aircraft and results in loss of signal or errors in time-of-arrival measurement. This undesired air -to-ground loading is a function of the number of interrogating aircraft in the vicinity of the serving transponder and the corresponding distribution of interrogation frequencies and signal amplitudes received at the transponder.

Note - Transponder to transponder garbling is controlled by the channel assignment authorities.

7.1.3 Up-link garble

Up-link garble occurs when valid replies at the interrogator are interfered with by other transponders and results in loss of signal or errors in pulse time-of-arrival measurement. The garble can be interference from any transponder whose frequency is within the bandwidth of the interrogator, including those on the same frequency, but with different pulse coding. This undesired ground-to- air loading is a function of the number of transponders in the vicinity of the interrogator and the corresponding distribution of reply frequencies and signal amplitudes received at the interrogator.

7.1.4 Interrogator processor efficiency

The interrogator signal processor efficiency is the ratio of the number of replies processed by the interrogator to the number of interrogations in the absence of garble and transponder dead time effects. This efficiency depends on the reply pulse threshold level and the receiver noise level.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 30

7.1.5 Relationship between aircraft served and transmission rate

7.1.5.1 Specification of the maximum transponder transmission rate establishes the maximum average transmitter power level. Chapter 3, 3.5.4.1.5.5 recommends that the transponder have a transmission rate capability of 2 700 pulse pairs per second if 100 aircraft are to be served. This represents typical transponder loading arising from

100 aircraft. To determine the actual transmission rate capability that should be accommodated at a given facility during peak traffic conditions requires that the maximum number of interrogators be estimated. To compute the interrogation loading on the transponder, the following should be considered:

- a) the number of aircraft that constitutes the peak traffic load;
- b) the number of interrogators in use on each aircraft;
- c) the distribution of operating modes of the interrogators in use (e.g. search, initial approach, final approach, ground test);
- d) the appropriate pulse repetition frequency as given in Chapter 3, 3.5.3.4.

7.1.5.2 Given the interrogation loading which results from the peak traffic as well as the reply efficiency of the transponder in the presence of this load, the resulting reply rate can be computed, thereby establishing the required transmitter capability. This reply rate is the level that, when exceeded, results in a reduction in receiver sensitivity (as specified in Chapter 3, 3.5.4.2.4) in order to maintain the reply rate at or below this maximum level.

7.1.6 (Reserved) Siting of DME associated with ILS or MLS.

7.1.7 Geographical separation criteria.

7.1.7.1 In order to allow consideration of actual antenna designs, equipment characteristics, and service volumes, the signal ratios needed to assure interference-free operation of the various facilities operating on DME channels are provided in 7.1.8 and 7.1.9. Given these ratios, the geographical separations of facilities may be readily evaluated by accounting for power losses over the propagation paths.

7.1.8 Desired to undesired (D/U) signal ratios at the airborne receiver

7.1.8.1 Table C-4 indicates the necessary D/U signal ratios needed to protect the desired transponder reply signal at an airborne receiver from the various co-frequency/adjacent frequency, same code/different code, undesired transponder reply signal combinations that may exist. The prerequisite for any calculation using the provided ratios is that the required minimum power density of the desired DME is met throughout the operationally published coverage volume. For initial assignments, the D/U ratios necessary to protect airborne equipment with 6-microsecond decoder rejection should be used. In making an assignment, each facility must be treated as the desired source with the other acting as the undesired. If both satisfy their unique D/U requirement, then the channel assignment may be made.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

7.1.8.2 Accordingly, DME channel assignments depend upon the following:

- a) For co-channel assignments: This condition occurs when both the desired and undesired signals operate on a channel (W, X, Y or Z) that is co-frequency, same code. The D/U signal ratio should be at least 8 dB throughout the service volume.
- b) For co-frequency, different code assignments: This condition occurs when one facility operates on an X channel with the other on a W channel. A similar Y channel and a Z channel combination also applies.
- c) For first adjacent frequency, same code assignments: This condition occurs when both the desired and undesired facilities are of W, X, Y or Z type.
- d) For first adjacent frequency, different code assignments: This condition occurs when one facility operates on an X channel with the other on a W channel, but with a frequency offset of 1 MHz between transponder reply frequencies. A similar Y channel and a Z channel combination also applies

Table C-4. Protection ratio D/U (dB)

Type of assignment	A	B
Co-frequency:		
Same pulse code	8	8
Different pulse code	8	-42
First adjacent frequency:		
Same pulse code	$-(P_u - 1)$	-42
Different pulse code	$-(P_u + 7)$	-75
Second adjacent frequency:		
Same pulse code	$-(P_u + 19)$	-75
Different pulse code	$-(P_u + 27)$	-75

Note 1 - The D/U ratios in column A protect those DME/N interrogators operating on X or Y channels. Column A applies to decoder rejection of 6 microseconds.

Note 2 - The D/U ratios in column B protect those DME/N or DME/P interrogators utilizing discrimination in conformance with 3.5.5.3.4.2 and 3.5.5.3.4.3 of Chapter 3 and providing a decoder rejection conforming to 3.5.5.3.5 of Chapter 3.

Note 3 - P_u is the peak effective radiated power of the undesired signal in dBW.

Note 4 - The frequency protection requirement is dependent upon the antenna patterns of the desired and undesired facility and the EIRP of the undesired facility.

Note 5 - In assessing adjacent channel protection, the magnitude of D/U ratio in column A should not exceed the magnitude of the value in column B.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 32

- e) For second adjacent frequency, same or different code assignments: The second adjacent frequency combinations generally need not be frequency protected. However, special attention should be given to Note 4 of Table C-4, especially if the undesired facility is a DME/P transponder.

7.1.9 Special considerations for DME Y and Z channel assignments

The channel assignment plan for DME is such that the transponder reply frequency for each Y or Z channel is the same as the interrogation frequency of another DME channel. Where the reply frequency of one DME matches the interrogation frequency of a second DME, the two transponders should be separated by a distance greater than the radio horizon distance between them. The radio horizon distance is calculated taking into account the elevations of the two transponder antennas.

7.1.10 (Reserved) Special considerations for DME/P associated with ILS

7.1.11 Considerations for the universal access transceiver (UAT)

7.1.11.1 Frequency planning criteria to ensure compatibility between DME and the UAT are contained in Part II of the *Manual on the Universal Access Transceiver (UAT)* (ICAO Doc 9861).

7.2 Guidance material concerning DME/N only

7.2.1 Coverage of DME/N

7.2.1.1 Whether a particular installation can provide the required frequency, protected coverage volume can be determined by using Figure C-20. The propagation loss for paths without obstructions uses the IF-77 propagation model.

7.2.1.2 Whenever a DME that provides coverage using either a directional or bi-directional DME antenna, the antenna pattern in azimuth and elevation has to be taken into account to achieve the full benefit of the reduced separation requirements outside the antennas main lobe. The actual radiation patterns of the antennas depend on a number of factors, including height of the antenna phase center, height of the DME counterpoise above ground level (AGL), terrain surface roughness, terrain form, site elevation above mean sea level (MSL), and conductivity of ground and counterpoise. For coverage under difficult terrain and siting conditions, it may be necessary to make appropriate increases in the equivalent isotropically radiated power (EIRP). Conversely, practical experience has shown, that under favourable siting conditions, and under the less pessimistic conditions often found in actual service, satisfactory system operation is achieved with a lower EIRP. However, to account for lowest EIRP in notches between the lobes of the real elevation antenna pattern, the values in Figure C-20 are recommended.

Note - Further guidance may be found in the Handbook on Radio Frequency Spectrum Requirements for Civil Aviation including statement of approved ICAO policies (ICAO Doc 9718).

7.2.2 EIRP of DME/N facilities

7.2.2.1 The power density figure prescribed in Chapter 3, 3.5.4.1.5.2 is based on the following example:

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

Airborne receiver sensitivity	-120 dBW
Transmission line loss, mismatch loss, antenna polar pattern variation with respect to an isotropic antenna	+9 dB
Power required at antenna	-111 dBW

Minus 111 dBW at the antenna corresponds to minus 89 dBW/m² at the mid-band frequency.

7.2.2.2 Nominal values of the necessary EIRP to achieve a power density of minus 89 dBW/m² are given in Figure C-20. For coverage under difficult terrain and siting conditions it may be necessary to make appropriate increases in the EIRP. Conversely, under favorable siting conditions, the stated power density may be achieved with a lower EIRP.

Figure C-20. Necessary EIRP to achieve a power density of -89 dBW/m² as a function of height above and distance from the DME

Note 1- The curves are based on the IF-77 propagation model with a 4/3 Earth radius which has been confirmed by measurements.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of VOR, NDB and DME	Attachment C	Page: 34

Note 2 - The radio horizon in Figure C-20 is for a DME antenna located 5 m (17 ft) AGL over flat terrain. Terrain shielding will reduce the achievable range.

Note 3 - If the antenna is located significantly higher than the assumed reference antenna, the radio horizon and power density will increase.

7.2.3 DME-DME RNAV

7.2.3.1 There is an increasing use of DME to support area navigation (RNAV) operations. Although the use of DME to support RNAV operations does not impose any additional technical requirements on the DME system, it does raise some additional issues compared with the traditional use of DME with VOR to support conventional operations. These are examined briefly below.

7.2.3.2 DME/DME positioning is based on the aircraft RNAV system triangulating position from multiple DME ranges from DME facility locations in the aircraft database. The resulting accuracy of the position solution depends on the range to the DMEs and their relative geometry. Some additional measures are therefore necessary to ensure that the DME infrastructure is adequate to support the RNAV operation, i.e. that sufficient DMEs are available and that their location provides adequate geometry to meet the accuracy requirements. For approach and departure procedures, it is also necessary to confirm that there is adequate signal strength and that there are no false locks or unlocks due to multipath. When ensuring there are sufficient DMEs, it is also important to identify any critical DMEs (i.e. those which must be operational for the necessary performance to be assured).

7.2.3.3 Errors in published DME facility locations will result in RNAV position errors. It is therefore important that DME positions are correctly surveyed and that adequate procedures are in place to ensure that the location data are correctly published. For DME facilities collocated with VOR, the DME position should be separately surveyed and published if the separation distance exceeds 30 m (100 ft).

Note.— Specifications concerning data quality and publication of DME location information are given contained in PANS-AIM (Doc 10066), Appendix 1.

7.2.3.4 When using DME to support RNAV, scanning DME aircraft receivers usually do not check the DME identification. As a consequence, removing the identification of a DME during tests and maintenance operations does not guarantee that the signals will not be used operationally. Maintenance actions that may provide misleading information should be minimized.

Note 1 - Further guidance on flight inspection of DME-DME RNAV procedures is given in ICAO Doc 8071.

8. Material concerning power supply switch-over times

8.1 Power supply switch-over times for ground-based radio aids used in the vicinity of aerodromes

The power supply switch-over times for radio navigation aids and ground elements of communications systems are dependent on the type of runway and aircraft operations to be supported. Table C-9 indicates representative switch-over times which may be met by power supply systems currently available.

Table C-9. Power supply switch-over times for ground-based radio aids used at aerodromes

Type of runway	Aids requiring power	Maximum switch-over times (seconds)
Instrument approach	SRE	15
	VOR	15
	NDB	15
	D/F facility	15
Precision approach, Category I	ILS localizer	10
	ILS glide path	10
	ILS middle marker	10
	ILS outer marker	10
	PAR	10
Precision approach, Category II	ILS localizer	0
	ILS glide path	0
	ILS inner marker	1
	ILS middle marker	1
	ILS outer marker	10
Precision approach, Category III	(same as Category II)

ATTACHMENT D. INFORMATION AND MATERIAL FOR GUIDANCE IN THE APPLICATION OF THE GNSS STANDARDS AND RECOMMENDED PRACTICES

1. Definitions

Bi-binary. Bi-binary is known as “Manchester Encoding”. It is sometimes referred to as “Differential Manchester Encoding”.

Using this system, it is the transition of the edge that determines the bit.

Chip. A single digital bit of the output of a pseudo-random bit sequence.

Gold code. A class of unique codes used by GPS, which exhibit bounded cross-correlation and off-peak auto-correlation values.

Selective availability (SA). A set of techniques for denying the full accuracy and selecting the level of positioning, velocity and time accuracy of GPS available to users of the standard positioning service signal.

2.General

Standards and Recommended Practices for GNSS contain provisions for the elements identified in Chapter 3, 3.7.2.2.

Additional implementation guidance is provided in the *Global Navigation Satellite System (GNSS) Manual* (ICAO Doc 9849).

Note - Except where specifically annotated, GBAS guidance material applies to GRAS.

3.Navigation System Performance Requirements

3.1 Introduction

3.1.1 Navigation system performance requirements are defined in the *Performance-based Navigation (PBN) Manual* (ICAO Doc 9613) for a single aircraft and for the total system which includes the signal-in-space, the airborne equipment and the ability of the aircraft to fly the desired trajectory. These total system requirements were used as a starting point to derive GNSS signal-in-space performance requirements. In the case of GNSS, degraded configurations which may affect multiple aircraft are to be considered. Therefore, certain signal-in-space performance requirements are more stringent to take into account multiple aircraft use of the system.

3.1.2 Two types of approach and landing operations with vertical guidance (APV), APV-I and APV -II, use vertical guidance relative to a glide path, but the facility or navigation system may not satisfy all of the requirements associated with precision approach. These operations combine the lateral performance equal to that of an ILS Category I localizer with different levels of vertical guidance. Both APV-I and APV- II provide access benefits relative to a non-precision approach, and the service that is provided depends on the operational requirements and the SBAS infrastructure. APV-I and APV-II exceed the requirements (lateral and vertical) for current RNAV approaches using barometric altimetry, and the relevant on-board equipment will therefore be suitable for the conduct of barometric VNAV APV and RNAV non-precision approaches.

	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 37

3.2 Accuracy

3.2.1 GNSS position error is the difference between the estimated position and the actual position. For an estimated position at a specific location, the probability should be at least 95 per cent that the position error is within the accuracy requirement.

3.2.2 Stationary, ground-based systems such as VOR and ILS have relatively repeatable error characteristics, so that performance can be measured for a short period of time (e.g. during flight inspection) and it is assumed that the system accuracy does not change after the test. However, GNSS errors change over time. The orbiting of satellites and the error characteristics of GNSS result in position errors that can change over a period of hours. In addition, the accuracy itself (the error bound with 95 per cent probability) changes due to different satellite geometries. Since it is not possible to continually measure system accuracy, the implementation of GNSS demands increased reliance on analysis and characterization of errors. Assessment based on measurements within a sliding time window is not suitable for GNSS.

3.2.3 The error for many GNSS architectures changes slowly over time, due to filtering in the augmentation systems and in the user receiver. This results in a small number of independent samples in periods of several minutes. This issue is very important for precision approach applications, because it implies that there is a 5 per cent probability that the position error can exceed the required accuracy for an entire approach. However, due to the changing accuracy described in 3.2.2, this probability is usually much lower.

3.2.4 The 95 per cent accuracy requirement is defined to ensure pilot acceptance, since it represents the errors that will typically be experienced. The GNSS accuracy requirement is to be met for the worst-case geometry under which the system is declared to be available. Statistical or probabilistic credit is not taken for the underlying probability of particular ranging signal geometry.

3.2.5 Therefore, GNSS accuracy is specified as a probability for each and every sample, rather than as a percentage of samples in a particular measurement interval. For a large set of independent samples, at least 95 per cent of the samples should be within the accuracy requirements in Chapter 3, Table 3.7.2.4-1. Data is scaled to the worst-case geometry in order to eliminate the variability in system accuracy that is caused by the geometry of the orbiting satellites.

3.2.6 An example of how this concept can be applied is the use of GPS to support performance required for non-precision approach operations. Assume that the system is intended to support non-precision approaches when the horizontal dilution of precision (HDOP) is less than or equal to 6. To demonstrate this performance, samples should be taken over a long period of time (e.g. 24 hours). The measured position error g for each sample i is denoted g_i . This error is scaled to the worst-case geometry as $6 \times g_i / \text{HDOP}$. Ninety-five per cent of the scaled errors must be less than 220 m for the system to comply with the non-precision accuracy requirement under worst-case geometry conditions. The total number of samples collected must be sufficient for the result to be statistically representative, taking into account the decorrelation time of the errors.

3.2.7 A range of vertical accuracy values is specified for Category I precision approach operations which bounds the different values that may support an equivalent operation to ILS. A number of values have been derived by different groups, using different interpretations of the ILS standards. The lowest value from these derivations was adopted as a conservative value for GNSS; this is the minimum value given for the range. Because this value is conservative, and because GNSS error characteristics are different from ILS, it may be possible to achieve Category I operations using larger values of accuracy within the range. The larger values would result in increased availability for the operation. The maximum value in the range has been proposed as a suitable value, subject to validation.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

3.2.7.1 Requirements for position domain accuracy to support precision approach operations below Category I are not defined in the SARPs. GBAS service types intended to support operations with lower than Category I minima are required to meet the SIS accuracy requirements for Category I at a minimum. In addition, specific pseudo-range accuracy requirements apply to support the assessment of adequate performance during aircraft certification. The additional requirements on pseudo-range accuracy may be combined with geometry screening to ensure the resulting position domain accuracy is adequate for a given aeroplane design to achieve suitable landing performance. See Attachment D, 7.5.12.2.

Table D-1. GPS user positioning accuracy

	GPS user positioning accuracy 95% of time, global average
Horizontal position error	33 m (108 ft)
Vertical position error	73 m (240 ft)

3.2.8 The GPS SPS position error (Chapter 3, 3.7.3.1.1.1) accounts for the contribution of the space and control segment to position errors (satellite clock and ephemeris errors) only; it does not include the contributions of ionospheric and tropospheric delay model errors, errors due to multipath effects, and receiver measurement noise errors (Attachment D, 4.1.2). These errors are addressed in the receiver standards. The user positioning error at the output of ABAS-capable equipment is mainly driven by the GNSS receiver used.

3.2.8.1 For Basic GNSS receivers, the receiver qualification standards require demonstration of user positioning accuracy in the presence of interference and a model of selective availability (SA) to be less than 100 m (95 per cent of time) horizontally and 156 m (95 per cent of time) vertically. The receiver standards do not require that a Basic GNSS receiver applies the ionospheric correction described in Appendix B, 3.1.2.4.

Note - The term “Basic GNSS receiver” designates the GNSS avionics that at least meet the requirements for a GPS receiver as outlined in BCAR -10, Volume I and the specifications of RTCA/DO-208 as amended by United States Federal Aviation Administration (FAA) TSO-C129A, or EUROCAE ED-72A (or equivalent).

3.2.8.2 Since the discontinuation of SA, the representative user positioning accuracy of GPS has been conservatively estimated to be as shown in Table D-0. The numbers provided assume that the worst two satellites of a nominal 24 GPS satellite constellation are out of service. In addition, a 7 m (1 σ) ionospheric delay model error, a 0.25 m (1 σ) residual tropospheric delay error, and a 0.80 m (1 σ) receiver noise error are assumed. After discontinuation of SA (Attachment D, 1.), the dominant pseudo-range error for users of the GPS Standard Positioning Service is the ionospheric error that remains after application of the ionospheric corrections. This error is also highly variable and depends on conditions such as user geomagnetic latitude, level of solar activity (i.e. point of the solar cycle that applies), level of ionospheric activity (i.e. whether there is a magnetic storm, or not), elevation angle of the pseudo-range measurement, season of the year, and time of day. The ionospheric delay model error assumption reflected in Table D-0 is generally conservative; however, conditions can be found under which the assumed 7 m (1 σ) error during solar maximum would be inadequate.

3.2.9 SBAS and GBAS receivers will be more accurate, and their accuracy will be characterized in real time by the receiver using standard error models, as described in Chapter 3, 3.5, for SBAS and Chapter 3, 3.6, for GBAS or the specification of the EUROCAE/ED-259 (or equivalent).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 39

Note 1- The term “SBAS receiver” designates the GNSS avionics that at least meet the requirements for an SBAS receiver as outlined in BCAR -10, Volume I and the specifications of RTCA/DO-229D with Change 1 (or equivalent) or the specification of the EUROCAE/ED-259 (or equivalent).

Note 2.— The term “GBAS receiver” designates the GNSS avionics that at least meet the requirements for a GBAS receiver as outlined in BCAR -10, Volume I and the specifications of the RTCA, documents covering the applicable performance types amended by United States FAA TSO-C161 (or equivalent).

3.3 Integrity

3.3.1 Integrity is a measure of the trust that can be placed in the correctness of the information supplied by the total system. Integrity includes the ability of a system to provide timely and valid warnings to the user (alerts) when the system must not be used for the intended operation (or phase of flight).

3.3.2 To ensure that the position error is acceptable, an alert limit is defined that represents the largest position error allowable for a safe operation. The position error cannot exceed this alert limit without annunciation. This is analogous to ILS in that the system can degrade so that the error is larger than the 95th percentile but within the monitor limit.

3.3.3 The integrity requirement of the navigation system for a single aircraft to support en-route, terminal, initial approach, non-precision approach and departure is assumed to be $1 - 1 \times 10^{-5}$ per hour.

3.3.4 For satellite-based navigation systems, the signal-in-space in the en-route environment simultaneously serves a large number of aircraft over a large area, and the impact of a system integrity failure on the air traffic management system will be greater than with traditional navigation aids. The performance requirements in Chapter 3, Table 3.7.2.4-1, are therefore more demanding.

3.3.5 For APV and precision approach operations, integrity requirements for GNSS signal-in-space requirements of Chapter 3, Table 3.7.2.4-1, were selected to be consistent with ILS requirements.

3.3.6 Alert limits for typical operations are provided in Note 2 to Table 3.7.2.4-1. A range of alert limits is specified for precision approach operations, reflecting potential differences in system design that may affect the operation. In ILS, monitor thresholds for key signal parameters are standardized, and the monitors themselves have very low measurement noise on the parameter that is being monitored. With differential GNSS, some system monitors have comparably large measurement noise uncertainty whose impact must be considered on the intended operation. In all cases, the effect of the alert limit is to restrict the satellite-user geometry to one where the monitor performance (typically in the pseudorange domain) is acceptable when translated into the position domain.

3.3.7 The smallest precision approach vertical alert limit (VAL) value (10 m (33 ft)) was derived based on the monitor performance of ILS as it could affect the glide slope at a nominal decision altitude of 60 m (200 ft) above the runway threshold. By applying this alert limit, the GNSS error, under faulted conditions, can be directly compared to an ILS error under faulted conditions, such that the GNSS errors are less than or equal to the ILS errors. For those faulted conditions with comparably large measurement noise in GNSS, this results in monitor thresholds are more stringent than ILS.

3.3.8 The largest precision approach VAL value (35 m (115 ft)) was derived to ensure obstacle clearance equivalent to ILS for those error conditions which can be modelled as a bias during the final approach, taking into account that the aircraft decision altitude is independently derived from barometric pressure. An assessment has been conducted of the worst-case effect of a latent bias error equal to the alert limit of 35 m (115 ft), concluding that adequate obstacle clearance protection is provided on the approach and missed

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 40

approach (considering the decision altitude would be reached early or late, using an independent barometric altimeter). It is important to recognize that this assessment only addressed obstacle clearance and is limited to those error conditions which can be modelled as bias errors. Analysis has shown 35 m (115 ft) bias high and low conditions can be tolerated up to the approach speed category (Categories A through D) glide path angle limits in the *Procedures for Air Navigation Services — Aircraft Operations* (PANS-OPS, ICAO Doc 8168) without impinging on the ILS obstacle clearance surfaces.

3.3.9 Since the analysis of a 35 m (115 ft) VAL is limited in scope, a system-level safety analysis should be completed before using any value greater than 10 m (33 ft) for a specific system design. The safety analysis should consider obstacle clearance criteria and risk of collision due to navigation error, and the risk of unsafe landing due to navigation error, given the system design characteristics and operational environment (such as the type of aircraft conducting the approach and the supporting airport infrastructure). With respect to the collision risk, it is sufficient to confirm that the assumptions identified in 3.3.8 are valid for the use of a 35 m (115 ft) VAL. With respect to an unsafe landing, the principal mitigation for a navigation error is pilot intervention during the visual segment. Limited operational trials, in conjunction with operational expertise, have indicated that navigation errors of less than 15 m (50 ft) consistently result in acceptable touchdown performance. For errors larger than 15 m (50 ft), there can be a significant increase in the flight crew workload and potentially a significant reduction in the safety margin, particularly for errors that shift the point where the aircraft reaches the decision altitude closer to the runway threshold where the flight crew may attempt to land with an unusually high rate of descent. The hazard severity of this event is major (see the *Safety Management Manual (SMM)* (ICAO Doc 9859)). One acceptable means to manage the risks in the visual segment is for the system to comply with the following criteria:

- a) the fault-free accuracy is equivalent to ILS. This includes system 95 per cent vertical navigation system error (NSE) less than 4 m (13 ft), and a fault-free system vertical NSE exceeding 10 m (33 ft) with a probability less than 10^{-7} for each location where the operation is to be approved. This assessment is performed over all environmental and operational conditions under which the service is declared available;
- b) under system failure conditions, the system design is such that the probability of an error greater than 15 m (50 ft) is lower than 10^{-5} , so that the likelihood of occurrence is remote. The fault conditions to be taken into account are those affecting either the core constellations or the GNSS augmentation under consideration. This probability is to be understood as the combination of the occurrence probability of a given failure with the probability of detection for applicable monitor(s). Typically, the probability of a single fault is large enough that a monitor is required to satisfy this condition.

3.3.10 For GBAS, a technical provision has been made to broadcast the alert limit to aircraft. For SBAS, technical provisions have been made to specify the alert limit through an updatable database (see Attachment C).

3.3.10.1 For GBAS approach service type D (see section 7.1.2.1) additional lower level performance and functional requirements are introduced in order to achieve a total system capable of supporting aircraft landing operations. This service type also supports guided take-off operations.

3.3.11 The approach integrity requirements apply in any one landing and require a fail-safe design. If the specific risk on a given approach is known to exceed this requirement, the operation should not be conducted. One of the objectives of the design process is to identify specific risks that could cause misleading information and to mitigate those risks through redundancy or monitoring to achieve a fail-safe design. For example, the ground system may need redundant correction processors and to be capable of shutting down automatically if that redundancy is not available due to a processor fault.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

3.3.12 A unique aspect of GNSS is the time-varying performance caused by changes in the core satellite geometry. A means to account for this variation is included in the SBAS and GBAS protocols through the protection level equations, which provide a means to inhibit use of the system if the specific integrity risk is too high.

3.3.13 GNSS performance can also vary across the service volume as a result of the geometry of visible core constellation satellites. Spatial variations in system performance can further be accentuated when the ground system operates in a degraded mode following the failure of system components such as monitoring stations or communication links. The risk due to spatial variations in system performance should be reflected in the protection level equations, i.e. the broadcast corrections.

3.3.14 GNSS single-frequency augmentations are also subject to several atmospheric effects, particularly due to the ionosphere. Spatial and temporal variations in the ionosphere will affect mostly single-frequency navigation because they can cause local or regional ionospheric delay errors that cannot be corrected within the L1 SBAS or GBAS architectures due to the definition of the message protocols and the sparse sampling of augmentation systems. Such events are rare and their likelihood varies by region, but they are not expected to be negligible. The resulting errors can be of sufficient magnitude to cause misleading information and should be mitigated in the system design through accounting for their effects in the broadcast parameters (e.g. σ_{iono_vert} in GBAS), and monitoring for excessive conditions where the broadcast parameters are not adequate. The likelihood of encountering such events should be considered when developing any system monitor. SBAS dual-frequency augmentations use ionosphere-free pseudo-ranges in order to remove the first order ionosphere delay in the position computation. The dual-frequency protection level includes a small error allocation to bound the residual ionosphere errors and greatly reduce the impact of local and temporal variations in ionospheric delays on the navigation solution.

3.3.15 Another environmental effect that should be accounted for in the ground system design is the errors due to multipath at the ground reference receivers, which depend on the physical environment of monitoring station antennas as well as on satellite elevations and times in track

3.3.16 SBAS needs to assure the integrity of its broadcast corrections as required in Chapter 3, 3.7.2.4, throughout its coverage area. This requirement also applies outside the intended service area, where user receivers could navigate using either an SBAS navigation solution, if available, or L1 fault detection and exclusion (FDE) navigation solution that combines satellites with SBAS corrections and satellites without SBAS corrections. DFMC SBAS corrections are not intended for use in an FDE navigation solution. The L1 SBAS contributions to a single-frequency FDE navigation solution are limited to assuring the integrity of the transmitted corrections. SBAS systems have to comply with all the integrity requirements for all typical operations from En-route to Category I, defined in Chapter 3, Table 3.7.2.4-1, in the coverage area when, for a given operation, the horizontal and vertical protection levels are lower than the corresponding alert limits. This is of particular importance for vertically guided operations using SBAS that are not controlled by FAS data block.

3.4 Continuity of service

3.4.1 Continuity of service of a system is the capability of the system to perform its function without unscheduled interruptions during the intended operation.

3.4.2 En-route

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 42

3.4.2.1 For en-route operations, continuity of service relates to the capability of the navigation system to provide a navigation output with the specified accuracy and integrity throughout the intended operation, assuming that it was available at the start of the operation. The occurrence of navigation system alerts, either due to rare fault-free performance or to failures, constitute continuity failures. Since the durations of these operations are variable, the continuity requirement is specified as a probability on a per-hour basis.

3.4.2.2 The navigation system continuity requirement for a single aircraft is $1 - 1 \times 10^{-4}$ per hour. However, for satellite-based systems, the signal-in-space may serve a large number of aircraft over a large area. The continuity requirements in Chapter 3, Table 3.7.2.4-1, represent reliability requirements for the GNSS signal-in-space, i.e. they derive mean time between outage (MTBO) requirements for the GNSS elements.

3.4.2.3 A range of values is given in Chapter 3, Table 3.7.2.4-1, for the signal-in-space continuity requirement for en-route operations. The lower value is the minimum continuity for which a system is considered to be practical. It is appropriate for areas with low traffic density and airspace complexity. In such areas, the impact of a navigation system failure is limited to a small number of aircraft, and there is, therefore, no need to increase the continuity requirement significantly beyond the single aircraft requirement ($1 - 1 \times 10^{-4}$ per hour). The highest value given (i.e. $1 - 1 \times 10^{-8}$ per hour) is suitable for areas with high traffic density and airspace complexity, where a failure will affect a large number of aircraft. This value is appropriate for navigation systems where there is a high degree of reliance on the system for navigation and possibly for dependent surveillance. The value is sufficiently high for the scenario based on a low probability of a system failure during the life of the system. Intermediate values of continuity (e.g. $1 - 1 \times 10^{-6}$ per hour) are considered to be appropriate for areas of high traffic density and complexity where there is a high degree of reliance on the navigation system but in which mitigation for navigation system failures is possible. Such mitigation may be through the use of alternative navigation means or the use of ATC surveillance and intervention to maintain separation standards. The values of continuity performance are determined by airspace needs to support navigation where GNSS has either replaced the existing navigation aid infrastructure or where no infrastructure previously existed.

3.4.3 Approach and landing

3.4.3.1 For approach and landing operations, continuity of service relates to the capability of the navigation system to provide a navigation output with the specified accuracy and integrity during the approach and landing, given that it was available at the start of the operation. In particular, this means that loss of continuity events that can be predicted and for which NOTAMs have been issued do not have to be taken into account when establishing compliance of a given system design against the SARPs continuity requirement. The occurrence of navigation system alerts, either due to rare fault-free performance or to failures, constitutes a loss of continuity event. In this case, the continuity requirement is stated as a probability for a short exposure time.

3.4.3.2 The continuity requirements for approach and landing operations represent only the allocation of the requirement between the aircraft receiver and the non-aircraft elements of the system. In this case, no increase in the requirement is considered necessary to deal with multiple aircraft use of the system. The continuity value is normally related only to the risk associated with a missed approach and each aircraft can be considered to be independent. However, in some cases, it may be necessary to increase the continuity values since a system failure has to be correlated between both runways (e.g. the use of a common system for approaches to closely-spaced parallel runways).

3.4.3.3 For GNSS-based APV and Category I approaches, missed approach is considered a normal operation, since it occurs whenever the aircraft descends to the decision altitude for the approach and the pilot is unable to continue with visual reference. The continuity requirement for these operations applies to the average risk

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 43

(over time) of loss of service, normalized to a 15-second exposure time. Therefore, the specific risk of loss of continuity for a given approach could exceed the average requirement without necessarily affecting the safety of the service provided or the approach. A safety assessment performed for one system led to the conclusion that, in the circumstances specified in the assessment, continuing to provide the service was safer than withholding it.

3.4.3.4 For those areas where the system design does not meet the average continuity risk specified in the SARPs, it is still possible to publish procedures. However, specific operational mitigations should be put in place to cope with the reduced continuity expected. For example, flight planning may not be authorized based solely on a GNSS navigation means with such a high average continuity risk.

3.5 Availability

3.5.1 The availability of GNSS is characterized by the portion of time the system is to be used for navigation during which reliable navigation information is presented to the crew, autopilot, or other system managing the flight of the aircraft.

3.5.2 When establishing the availability requirements for GNSS, the desired level of service to be supported should be considered. If the satellite navigation service is intended to replace an existing en-route navigation aid infrastructure, the availability of the GNSS should be commensurate with the availability provided by the existing infrastructure. An assessment of the operational impact of a degradation in service should be conducted.

3.5.3 Where GNSS availability is low, it is still possible to use the satellite navigation service by restricting the navigation operating times to those periods when it is predicted to be available. This is possible in the case of GNSS since unavailability due to insufficient satellite geometry is repeatable. Under such restrictions, there remains only a continuity risk associated with the failure of necessary system components between the time the prediction is made and the time the operation is conducted.

3.5.4 En-route

3.5.4.1 Specific availability requirements for an area or operation should be based upon:

- a) traffic density and complexity;
- b) alternate navigation aids;
- c) primary/secondary surveillance coverage;
- d) air traffic and pilot procedures; and
- e) duration of outages.

3.5.4.2 For this reason, the GNSS SARPs specify a range of values for availability requirements. The requirements support GNSS sole-means operations in airspace with various levels of traffic and complexity. The lower end of the range is only sufficient for providing sole means of navigation in a low traffic density and complexity airspace.

3.5.4.3 While augmentations can reduce the dependency of the GNSS on a particular core element, they do not provide usable service without the core elements. The requirement for the availability of a particular augmentation in an area should account for potential degradation in the GNSS core elements (i.e. the

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 44

minimum constellation of core elements (number and diversity of satellites) that is expected). Operational procedures should be developed in case such a degraded configuration occurs.

3.5.5 Approach

3.5.5.1 Specific requirements for an area should be based upon:

- a) traffic density and complexity;
- b) procedures for filing and conducting an approach to an alternate airport;
- c) navigation system to be used for an alternate airport;
- d) air traffic and pilot procedures;
- e) duration of outages; and
- f) geographic extent of outages.

3.5.5.2 When developing operating procedures for GNSS approach systems, the duration of an outage and its impact on the alternate airport should be considered. Although GNSS outages can occur which affect many approaches, the approach service can be restored without any maintenance because of the orbiting of the satellites.

3.5.6 Determining GNSS availability

Note.— Additional guidance material pertaining to reliability and availability of radio communications and navigation aids is contained in Attachment F.

3.5.6.1 The availability of GNSS is complicated by the movement of satellites relative to a coverage area under consideration and the potentially long time needed to restore a satellite in the event of a failure. Accurately measuring the availability would require many years to allow for a measurement period longer than the MTBF and repair times. The availability of GNSS should be determined through design, analysis and modeling, rather than measurement. The availability model should account for the ionospheric, tropospheric and receiver error models used by the receiver to verify integrity (e.g. HPL, LPL and VPL calculations). The availability specified in Chapter 3, 3.7.2.4, applies to the design availability.

3.5.6.2 The availability of ABAS, GBAS and SBAS must be evaluated by comparing the augmented performance to the operational requirements of Chapter 3, 3.7.2.4. The availability of ABAS, GBAS and SBAS does not directly relate to the core constellation service availability standards in Chapter 3. Availability analysis is based on the number of usable satellites from the core constellation(s) and the performance of the augmentation system(s). Information on the operational satellites/slots is given in the satellite/slot/constellation availability standards or guidance material for each core constellation.

4. GNSS Core Elements

4.1 Core constellations

4.1.1 GPS

Note - Additional information concerning GPS can be found in the GPS APS PS K, and IS-GPS-705F.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 45

4.1.1.1 The L1 C/A code performance standards are based upon the assumption that a representative standard positioning service (SPS) receiver is used. A representative receiver has the following characteristics:

- a) designed in accordance with IS-GPS-200 K;
- b) tracking the SF L1 C/A code SPS SIS from all satellites in view above uses a 5-degree masking angle;
- c) accomplishes satellite position and geometric range computations in the most current realization of the World Geodetic System 1984 (WGS-84) Earth-Centred, Earth-Fixed (ECEF) coordinate system;
- d) generates a position and time solution from data broadcast by all satellites in view transmitting PRNs 1-32;
- e) compensates for dynamic Doppler shift effects on nominal SPS ranging signal carrier phase and C/A code measurements;
- f) excludes marginal and unhealthy satellites from the position solution;
- g) uses up-to-date and internally consistent ephemeris and clock data within the respective curve fit intervals for all satellites it is using in its position solution; and
- h) loses track in the event that a GPS satellite stops transmitting a trackable signal.

The time transfer accuracy applies to the data in the broadcast navigation message, which relates GPS SPS time to UTC as maintained by the United States Naval Observatory. A 12-channel receiver will meet performance requirements specified in Chapter 3, 3.7.3.1.1.1 and 3.7.3.1.1.2. A receiver that is able to track four satellites only (Appendix B, 3.1.1.3.1.2) will not get the full position domain accuracy and availability performance.

Note 1.— No user position domain performance standards are available at this time for L5-only operation because there are no SIS availability or continuity performance standards defined yet for the L5 signals. Availability and continuity performance standards for the L5 signals will be provided in advance of any declaration for an enhanced SPS which includes the L5 service. The performance standards for the L5 signals (range domain accuracy, reliability, major service failure) are at the SIS level and do not require the notion of a user receiver. However, it may be helpful when considering the accuracy and integrity standards for the L5 signals to consider that a user receiver would need to be designed to process the L5 signals in a manner analogous to how it processes the L1 signals; particularly by processing those signals in accordance with IS-GPS-705, continuously monitoring the L5 SIS health, using up-to-date and internally consistent navigation data (CNAV), and using only satellites designated as healthy during normal GPS operations.

Note 2 - Conditions indicating that a satellite is “healthy”, “marginal” or “unhealthy” can be found in the the GPS SPS PS, Section 2.3.2.

4.1.1.2 Position domain accuracy. The position domain accuracy is measured with a representative receiver and a measurement interval of 24 hours for any point within the coverage area. The positioning and timing accuracy are for the signal-in-space (SIS) only and do not include such error sources as: ionosphere, troposphere, interference, receiver noise or multipath. In order to maintain backwards compatibility, the

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 46

position domain accuracy standard will be met with a representative SPS receiver tracking only PRNs 1 through 32.

4.1.1.3 Range domain accuracy. The range domain accuracy standard applies to normal operations, which implies that updated navigation data is uplinked to the satellites on a regular basis. Range domain accuracy is conditioned by the satellite transmitting a healthy status and transmitting C/A code and does not account for satellite failures outside of the normal operating characteristics. Range domain accuracy limits can be exceeded during satellite failures or anomalies while uploading data to the satellite. The range rate error limit is the maximum for any satellite measured over any 3-second interval for any point within the coverage area. The range acceleration error limit is the maximum for any satellite measured over any 3-second interval for any point within the coverage area. Under nominal conditions, all satellites are maintained to the same standards, so it is appropriate for availability modelling purposes to assume that all satellites have a 43.6 - meter RMS SIS user range error (URE). The standards are restricted to range domain errors allocated to space and control segments.

4.1.1.4 Availability. The availability standard applies to normal operations, which implies that updated navigation data is uplinked to the satellites on a regular basis. Availability is the percentage of time over any 24-hour interval that the predicted 95 per cent positioning error (due to space and control segment errors) is less than its threshold, for any point within the coverage area. It is based on a 15-meter horizontal 95 per cent threshold; a 33-meter vertical 95 per cent threshold; using a representative receiver; and operating within the coverage area over any 24-hour interval. The service availability assumes a constellation that meets the criteria in Chapter 3, 3.7.3.1.1.7. As noted for position domain accuracy, in order to maintain backwards compatibility, the availability standard will be met with a representative SPS receiver tracking only PRNs 1 through 32.

4.1.1.5 Reliability. Reliability is the percentage of time over a specified time interval that the instantaneous SPS SIS URE is maintained within the range error limit, at any given point within the coverage area, for all healthy GPS satellites. The reliability standard is based on a measurement interval of one year and the average of daily values within the coverage area. The worst single point average reliability assumes that the total service failure time of 18 hours will be over that particular point (3 failures each lasting 6 hours).

4.1.1.6 Major service failure.

4.1.1.6.1 A major service failure is defined to be a condition over a time interval during which a healthy GPS satellite's instantaneous ranging signal error (excluding atmospheric and receiver errors) exceeds the range error limit of 4.42 times the user range accuracy (URA) broadcast by a satellite for longer than the allowable time to alert (10 seconds). A major service failure occurs only if no alert is issued within the 10 second time to alert. Events when the instantaneous user range error (URE) exceeds 4.42 times the IAURA for a total duration of less than 10 seconds are not counted as major service failures. Once an alert has been issued, the major service failure event ceases to have any impact on SPS SIS integrity.

4.1.1.6.2 The instantaneous SIS URE will depend upon the combination of SIS components used. The major service failure standards apply for both single-frequency and dual-frequency users using these SIS component combinations in Table D-X.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

Table D-2. GPS SPS SIS component combinations

<i>One carrier, single-frequency (SF)</i>	<i>Two carriers, dual-frequency (DF)</i>
C/A-code + LNAV data	(C/A + I5)-codes + CNAV data
I5-code + CNAV data	(C/A + Q5)-codes + CNAV data
Q5-code + CNAV data	(C/A + I5+Q5)-codes + CNAV data
(I5+Q5)-codes + CNAV data	

4.1.1.6.3 For SIS component combinations using LNAV data, the IAURA is equal to the upper bound on the URA value corresponding to the URA index “N” currently broadcast by the satellite in subframe 1. This URA is specific to the broadcasting satellite. For SIS component combinations using CNAV data, the IAURA is the root sum square (RSS) of an elevation-dependent function of the upper bound value of the URA_{ED} component and a non-elevation-dependent function of the upper bound value of the URA_{NED} component currently broadcast by the satellite in MT-10 and MT-3x respectively. This IAURA is also specific to the broadcasting satellite. The IAURA for a marginal SPS SIS is not defined and there is no IAURA for an unhealthy SPS SIS. Since the URAs and IAURAs vary with time, a validity period for each is specified in the GPS interface specifications.

4.1.1.6.4 The onset rate, R_{sat} , is defined as the probability of a major service failure on any particular satellite over any hour, given that the maximum SPS SIS instantaneous URE did not exceed 4.42 times the IAURA at the start of the hour. The mean fault duration is one hour and the worst-case duration is six hours.

4.1.1.6.5 The probabilities of a single satellite major service failure (P_{sat}) for a particular satellite and a common-cause, multi-satellite major service failure (P_{const}) are instantaneous state probabilities equivalent to the fraction of time when the SPS SIS instantaneous URE exceeds 4.42 times the IAURA for more than 10 seconds without an alert issued within those 10 seconds.

4.1.1.6.6 The probability of 1×10^{-5} in Chapter 3, 3.7.3.1.1.4 corresponds to a maximum of 3 major service failures, with one-hour duration for the entire constellation per year assuming a maximum constellation of 32 satellites:

4.1.1.7 Continuity. Continuity for a healthy GPS satellite is the probability that the SPS SIS will continue to be healthy without unscheduled interruption over a specified time interval. Scheduled interruptions which are announced at least 48 hours in advance do not contribute to a loss of continuity

4.1.1.8 Coverage. The SPS supports the terrestrial coverage area, which is from the surface of the earth up to an altitude of 3 000 km.

4.1.1.9 *Normal operations.* In normal operations mode, the satellites are uploaded with fresh navigation (NAV) message data by the control segment on a regular basis. The SPS SIS indicates when the satellite is in the normal operations mode by way of the C/A code signal LNAV data stream fit interval flag being set to “0” (zero) in accordance with IS-GPS-200K. When the fit interval flag is set to “1” (one), the satellite is operating in the extended operations mode. Special SPS SIS accuracy standards apply for the extended operations mode. See IS-GPS-200K for further details on the fit interval flag.

Note 1.— There is no equivalent “normal operations mode” flag (fit interval flag) in the CNAV data stream on the I5-code signal

Note 2.— Additional information concerning normal operations is given in the GPS SPS PS, Sections A.4.3.2 and A.4.3.3.

4.1.2 GLONASS

Note - Additional information is given in the GLONASS FDMA ICD and in the GLONASS CDMA ICD General Description.

4.1.2.1 Assumptions. The performance standard is based upon the assumption that a representative channel of standard accuracy (CSA) receiver is used. A representative receiver has the following characteristics: designed in accordance with GLONASS ICD; uses a 5-degree masking angle; accomplishes satellite position and geometric range computations in the most current realization of the PZ-90 and uses PZ-90 – WGS-84 transformation parameters as indicated in Appendix B, 3.2.5.2; generates a position and time solution from data broadcast by all satellites in view; compensates for dynamic Doppler shift effects on nominal CSA ranging signal carrier phase and standard accuracy signal measurements; excludes GLONASS unhealthy satellites from the position solution; uses up-to-date and internally consistent ephemeris and clock data for all satellites it is using in its position solution; and loses track in the event that a GLONASS satellite stops transmitting standard accuracy code. The time transfer accuracy applies to a stationary receiver operating at a surveyed location.

4.1.2.2 Accuracy. Accuracy is measured with a representative receiver and a measurement interval of 24 hours for any point within the coverage area. The positioning and timing accuracy of single-frequency solutions are for the signal-in-space (SIS) only and do not include such error sources as: ionosphere, troposphere, interference, receiver noise or multipath. Dual-frequency solution accuracy characteristics include ionosphere residual errors. The accuracy is derived based on the worst two of 24 satellites being removed from the constellation and a 6-meter constellation RMS SIS user range error (URE).

4.1.2.3 Range domain accuracy. Range domain accuracy is conditioned by the satellite indicating a healthy status and transmitting standard accuracy code and does not account for satellite failures outside of the normal operating characteristics. Range domain accuracy limits can be exceeded during satellite failures or anomalies while uploading data to the satellite. Exceeding the range error limit constitutes a major service failure as described in 4.1.2.6. The range rate error limit is the maximum for any satellite measured over any 3-second interval for any point within the coverage area. The range acceleration error limit is the maximum for any satellite measured over any 3-second interval for any point within the coverage area. The range error accuracy over all satellites is the 95 per cent threshold of the URE of all satellites over any 24-hour interval for any point within the coverage area. The range error accuracy for any satellite is calculated over a 30-day interval. Under nominal conditions, all satellites are maintained to the same standards, so it is appropriate for availability modelling purposes to assume that all satellites have a 6-meter RMS SIS URE. The standards are restricted to range domain errors allocated to space and control segments.

4.1.2.4 Availability. Availability is the percentage of time over any 24-hour interval that the predicted 95 per cent positioning error (due to space and control segment errors) is less than its threshold, for any point within the coverage area. It is based on a 12-meter (40-foot) horizontal 95 per cent threshold and a 25-meter (80-foot) vertical 95 per cent threshold, using a representative receiver and operating within the coverage area over any 24-hour interval. The service availability assumes the worst combination of two satellites out of service.

4.1.2.4.1 Twenty-four operational satellites are available in orbit with 0.95 probability (averaged over any day), where a satellite is defined to be operational if it is capable of, but is not necessarily transmitting, a usable ranging signal. At least 21 satellites in the 24 nominal plane/slot positions must be set healthy and must be transmitting a navigation signal with 0.98 probability (yearly averaged).

4.1.2.5 Reliability. Reliability is the percentage of time over a specified time interval that the instantaneous CSA SIS URE is maintained within the range error limit, at any given point within the coverage area, for all healthy GLONASS satellites. The reliability standard is based on a measurement interval of one year and the average of

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

daily values within the coverage area. The single point average reliability assumes that the total service failure time of 18 hours will be over that particular point (three failures each lasting six hours).

4.1.2.6 Major service failure. A major service failure is defined as a condition over a time interval during which a single healthy GLONASS satellite’s ranging signal error (excluding atmospheric and receiver errors) exceeds the range error limit of 70 m (as defined in Chapter 3, 3.7.3.1.2.4).

4.1.2.7 *Constellation fault*. Constellation fault is defined as a condition over a time interval during which more than one healthy GLONASS satellite’s ranging signal error (excluding atmospheric and receiver errors) exceeds the range error limit of 70 m due to a common cause (as defined in Chapter 3, 3.7.3.1.2.5).

4.1.2.8 *Continuity*. Continuity for a healthy GLONASS satellite is the probability that the GLONASS SIS will continue to be healthy without unscheduled interruption over a specified time interval. Scheduled interruptions, which are announced at least 48 hours in advance, do not contribute to a loss of continuity.

4.1.2.9 Coverage. The GLONASS CSA supports the terrestrial coverage area, which is from the surface of the earth up to an altitude of 2 000 km.

4.1.2.10 GLONASS time. GLONASS time is generated based on GLONASS Central Synchronizer time. Daily instability of the Central Synchronizer hydrogen clock is not worse than 5×10^{-14} . The difference between GLONASS time and UTC(SU) is within 1 millisecond. The navigation message contains the requisite data to relate GLONASS time to UTC(SU) within 0.7 microsecond.

4.1.2.10.1 Transformation of GLONASS-M current data information into common form. A satellite navigation message contains current data information in N_T parameter. It could be transformed into the common form by the following algorithm:

a) Current year number J in the four-year interval is calculated:

```

If
1   ≤ NT ≤ 366;           J = 1;
If 367   ≤ NT ≤ 731;       J = 2;
If 732   ≤ NT ≤ 1 096;     J = 3;
If
1   097 ≤ NT ≤ 1 461;     J = 4.

```

b) Current year in common form is calculated by the following formula: $Y = 1\ 996 + 4(N_4 - 1) + (J - 1)$.

c) Current day and month (dd/mm) are extracted from the reference table stored in user equipment ROM. The table interrelates N_T parameter and common form dates.

4.1.2.11 GLONASS coordinate system. The GLONASS coordinate system is PZ-90 as described in Parameters of Earth, 1990 (PZ-90), published by the Topographic Service, Russian Federation Ministry of Defence, Moscow.

4.1.2.11.1 PZ-90 parameters include fundamental geodetic constants, dimensions of the common terrestrial ellipsoid, the characteristics of the gravitational field of the earth, and the elements of the Krasovsky ellipsoid (coordinate system 1942) orientation relative to the common terrestrial ellipsoid.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 50

4.1.2.11.2 By definition, the coordinate system PZ-90 is a geocentric Cartesian space system whose origin is located at the centre of the earth’s body. The Z-axis is directed to the Conventional Terrestrial Pole as recommended by the International Earth Rotation Service. The X-axis is directed to the point of intersection of the earth’s equatorial plane and zero meridian established by the Bureau International de l’Heure. The Y-axis completes the right-handed coordinate system.

4.1.2.11.3 Geodetic reference systems WGS 84 and PZ-90 are maintained consistent with the International Terrestrial Reference Frame (ITRF). While the current conversion parameters from PZ-90 to WGS 84 are provided in Appendix B, 3.2.5.2, the application of previous versions of these parameters is also appropriate as long as performance requirements of Chapter 3, Table 3.7.2.4-1 for intended operation are met.

4.1.3 Galileo

Note.— Additional information concerning the Galileo Open Service is given in the Galileo OS SIS ICD and Galileo OS SDD.

4.1.3.1 *Assumptions.* The Galileo Open Service (OS) performance standard is based upon the assumption that a representative OS receiver is used. A representative receiver has the following characteristics:

- a) designed in accordance with Galileo OS SIS ICD;
- b) uses a 5-degree masking angle;
- c) accomplishes satellite position and geometric range computations in the most current realization of the Galileo Terrestrial Reference Frame (GTRF);
- d) generates a position and time solution from data broadcast by all satellites in view;
- e) excludes Galileo non-healthy signals from the position solution;
- f) uses up-to-date and internally consistent ephemeris and clock data for all satellites it is using in its position solution; and
- g) navigation data (ephemeris, satellite clock correction and SISA parameters) is not used beyond the maximum validity time of 4 hours.

4.1.3.2 Position domain accuracy

4.1.3.2.1 *Position domain accuracy for single-frequency Galileo OS.* The horizontal/vertical position domain accuracy is measured with a representative receiver and a measurement interval of 30 days for any point within the coverage area. The position is computed using single-frequency “healthy” SIS. The positioning and timing accuracy are for the SIS only (including BGD errors) and do not include such error sources as: ionosphere, troposphere, interference, receiver noise or multipath.

4.1.3.2.2 *Position domain accuracy for dual-frequency Galileo OS.* The horizontal/vertical position domain accuracy is measured with a representative receiver and a measurement interval of 30 days for any point within the coverage area. The position is computed using dual-frequency “healthy” SIS. The positioning and timing accuracy are for the SIS only and do not include such error sources as: ionosphere, troposphere, interference, receiver noise or multipath.

4.1.3.3 *Range domain accuracy.* The Galileo ranging accuracy is defined as a statistical measure of the SIS range error time series. It is only measured for time periods during which the transmitted SIS is healthy. Galileo ranging accuracy is evaluated over all age of data (AOD) values, i.e. the SIS range error time series will consider the navigation message at the age of data when it was observed. It is computed for both single-frequency and dual-frequency users. The range rate error limit is the maximum for any satellite measured over any 3-second interval for any point within the coverage area. The 95th percentile SIS range error accuracy for any satellite is calculated over a 30-day interval. The 99.9th percentile SIS range error accuracy for any satellite is normalized annually.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

4.1.3.3.1 *SIS accuracy*. The SIS accuracy is a prediction of the minimum standard deviation (1-sigma) of the unbiased Gaussian distribution which overbounds the predictable distribution of SIS range error for all possible user locations within the satellite coverage area. The SISA parameter, broadcast in Galileo SIS navigation message, provides the user with an indication of the SIS accuracy according to Appendix B, 3.1.3.1.3.4.2. The SISA parameter can assume 255 values. Nevertheless, when it is used as one of the means for determining the SIS status of a Galileo satellite, it must be considered as a binary indicator with its only meaningful values being “no accuracy prediction available” (NAPA) when SISA=255 or “not NAPA” when SISA≠255. SISA values from 126 to 254 are described as spare, and should be considered as “not NAPA”.

4.1.3.3.2 *Galileo BGD*. Galileo BGD is the estimate of the group delay between the different frequencies of a specific Galileo satellite. It is provided as part of the Galileo broadcast navigation data as specified in Appendix B, 3.1.3.1.3.1 and 3.1.3.1.3.2.

4.1.3.4 *Galileo UTC time determination accuracy*. The Galileo UTC time determination accuracy depends on both the instantaneous GST determination error and on the error in the broadcast GST-UTC conversion parameters. This second component is defined as the Galileo SIS UTC time dissemination accuracy.

4.1.3.4.1 *Galileo SIS UTC time dissemination accuracy*. The Galileo SIS UTC time dissemination accuracy is defined as the 95th percentile of the broadcast GST/UTC conversion parameters error. Galileo SIS UTC time dissemination accuracy is the SIS component of the overall user UTC time determination, which is driven by the accuracy of the broadcast GST-UTC parameters. It does not contain effects that are not under the control of the Galileo operator such as user local contributions depending on the receivers or due to atmospheric effects.

4.1.3.5 *Service availability*. Service availability is the percentage of time over a 30-day interval that the predicted 95 per cent positioning error (due to space and control segment errors) is less than its threshold, for any point within the coverage area. It is based on a 10-metre horizontal 95 per cent threshold; a 16-metre vertical 95 per cent threshold; using a representative receiver; and operating within the coverage area over the 30-day interval. The service availability assumes a constellation that meets the criteria in 4.1.3.5.1.

4.1.3.5.1 *SIS per-slot/constellation availability*. The probability that an operational slot in the Galileo constellation is occupied by a satellite transmitting healthy SIS is higher than 0.95 (normalized annually). For the Galileo baseline configuration, the probability that at least 21 satellites in the nominal 24-slot positions are set healthy and are transmitting a navigation signal, is higher than 0.97 (normalized annually). The SIS constellation availability can be derived from the SIS per-slot availability by means of a binomial model.

4.1.3.6 Probability of failure

4.1.3.6.1 *Psat*. Psat is the probability that the instantaneous ranging signal error of a healthy Galileo satellite (excluding atmospheric and receiver errors) exceeds k times the Galileo user range accuracy (Galileo URA). Galileo URA in Psat definition corresponds to $\sigma_{URA,DF}$ or to $\sigma_{URA,SF}$ for dual-frequency or single-frequency users, respectively. k is the number of standard deviations from the mean corresponding to a probability of Psat in a normal distribution. The k factor is 4.17, corresponding to the 3×10^{-5} Psat value. Psat applies at any given time and at any location in the satellite visibility area to both single-frequency and dual-frequency users.

4.1.3.6.2 *Pconst*. *Pconst* is the probability that the instantaneous ranging signal errors of two or more healthy Galileo satellites (excluding atmospheric and receiver errors) exceeds *k* times the Galileo user range accuracy (Galileo URA) due to a common failure. Galileo URA in the *Pconst* definition corresponds to $\sigma_{URA,DF}$ or to $\sigma_{URA,SF}$ for dual-frequency or single-frequency users, respectively. *Pconst* applies at any given time and at any location in the respective visibility areas of the affected satellites to both single-frequency and dual-frequency users.

4.1.3.6.3 $\sigma_{URA,DF}$. Galileo $\sigma_{URA,DF}$ is defined as the standard deviation of a zero-mean normal distribution which overbounds the actual distribution of SIS range errors more probable than *P*_{sat}. Galileo $\sigma_{URA,DF}$ applies to any user location and to a healthy SIS dual-frequency combination E1/E5a.

4.1.3.6.4 $\sigma_{URA,SF}$. Galileo $\sigma_{URA,SF}$ is defined as the standard deviation of a zero-mean normal distribution which overbounds the actual distribution of SIS range errors more probable than *P*_{sat}. Galileo $\sigma_{URA,SF}$ applies to any user location and to a healthy SIS single-frequency user (E1 or E5a). $\sigma_{URA,SF}$ considers the Galileo σ_{BGD} and can be derived from the following expression:

$$\sigma_{URA,SF}^2 = \sigma_{URA,DF}^2 + \gamma_f^2 \cdot \sigma_{BGD}^2$$

where

γ_f represents the frequency inflation factor equal to f_{E1}^2/f_{E5a}^2 for E5a users and to 1 for E1 users.

4.1.3.6.5 σ_{BGD} . Galileo σ_{BGD} is defined as the standard deviation of a zero-mean normal distribution, which overbounds the actual distribution of BGD residual errors such that the probability of unbounded errors is negligible with respect to *P*_{sat}. BGD residual errors are the remaining errors after applying Galileo BGD corrections broadcast in the navigation message.

4.1.3.7 *Continuity*. Continuity for a healthy Galileo satellite is the probability that the Galileo OS SIS will continue to be healthy without unscheduled interruption over the next hour. Scheduled interruptions which are announced at least 48 hours in advance do not contribute to a loss of SIS continuity.

4.1.3.8 *Coverage*. The Galileo OS supports the terrestrial coverage area, which is from the surface of the earth up to 30.48 km.

4.1.3.9 *Galileo system time (GST)*. The GST is a continuous timescale based on the definition of the second (according to the International System of units, SI) whose origin/reference epoch GST (t₀) is defined as 13 seconds before 1999-08-22 00:00:00 UTC. The time synchronization information disseminated in the Galileo SIS (e.g. satellite clock offsets) is referenced to GST. This information allows the Galileo OS users to estimate their local time referenced to the GST realization computed by the Galileo OS receiver. In order to better support timing applications based on UTC, the Galileo OS data message includes additional parameters which enable the Galileo OS users to obtain a realization of the UTC time by applying a correction to the GST.

4.1.3.10 *Galileo terrestrial reference frame (GTRF)*. The GTRF is a highly accurate independent realization of the International Terrestrial Reference System (ITRS) based on the estimated coordinates of each of the Galileo sensor station (GSS) sites. The Galileo system uses the geodetic input information to produce navigation data (e.g. satellite ephemeris) referenced to the GTRF. Accordingly, the user position coordinates derived from

Galileo position solutions are referenced to GTRF. Due to the good alignment of GTRF to ITRF both reference frames are understood to be equivalent for aviation. The GTRF is regularly aligned if new ITRF realizations are published. To obtain the position in any reference frame different from ITRF, Galileo OS user equipment needs to apply the appropriate valid transformation parameters between the latest ITRF and the desired reference frame. This transformation is under full control and responsibility of the Galileo OS user. Concerning the interoperability between GPS and Galileo, the GPS terrestrial reference frame WGS-84 and the GTRF are both realizations of the ITRF. Therefore, for most Galileo OS applications, a high level of interoperability is provided between the spatial positions obtained with GPS and those obtained with Galileo, without further activity by the user equipment.

4.1.3.11 *Age of ephemeris.* The age of ephemeris is the time elapsed between the reference toe (set at the beginning of each navigation data set) and the time of usage of the ephemeris by a receiver.

Note.— Details on how to compute the age of ephemeris can be found in Galileo OS SDD, Annex C, section 4.4.1.

4.1.3.12 *Age of data (AOD).* The age of data (AOD) is the elapsed time between the generation of a navigation message by the ground segment and its usage at user level. Aging of data (characterized by AOD) impacts the accuracy of the orbit and clock models. The accuracy of their prediction inevitably degrades with higher ages.

4.1.4 BDS

4.1.4.1 *Assumptions.* The performance standard is based upon the assumption that a representative BDS Open Service (BDS OS) receiver is used. A representative receiver has the following characteristics: it is designed in accordance with BDS ICDs; uses a 5-degree masking angle for MEO satellites and a 12-degree masking angle for IGSO satellites; accomplishes satellite position and geometric range computations in the most current realization of the BDCS (which is equivalent to WGS-84); compensates for dynamic Doppler shift effects on nominal BDS OS ranging signal carrier phase and ranging code measurements; excludes BDS unhealthy or marginal satellites from the position solution; uses up-to-date and internally consistent ephemeris and clock data for all satellites it is using in its position solution; and loses track in the event that a BDS satellite stops transmitting ranging code. The time transfer accuracy applies to a stationary receiver operating at a surveyed location.

4.1.4.2 *Accuracy.* Position domain accuracy is measured with a representative receiver and a measurement interval of 168 hours (seven sidereal days) for any point within the coverage area. The positioning and timing accuracy are for the SIS only and do not include such error sources as: ionosphere, troposphere, interference, receiver noise or multipath. The accuracy is derived based on the worst two of all operational satellites being removed from the constellation and a 4.6-metre 95th percentile user range error of any satellite.

4.1.4.2.1 *Time transfer accuracy.* Time transfer accuracy is the 95 per cent statistical deviation between the BDS OS timing receiver output and Coordinated Universal Time (UTC) maintained by NTSC in China. It can be used to evaluate the timing performance of a navigation satellite system.

4.1.4.3 *Range domain accuracy.* Range domain accuracy is measured with a representative receiver and a measurement interval of 168 hours. Range domain accuracy is conditioned by the satellite indicating a healthy status and transmitting BDS OS ranging code and does not account for satellite failures outside of the normal operating characteristics. Range domain accuracy limits can be exceeded during satellite failures or anomalies while uploading data to the satellite. Exceedance of the range error limit constitutes a major service failure as described in 4.1.4.5. The range rate error limit is the maximum for any satellite measured over any 3-second

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 54

interval for any point within the coverage area. The range acceleration error limit is the maximum for any satellite measured over any 3-second interval for any point within the coverage area. Under nominal conditions, all satellites are maintained to the same standards, so it is appropriate for availability modelling purposes to assume that all satellites have a 4.6-metre 95th percentile user range error. The standards are restricted to range domain errors allocated to space and control segments.

4.1.4.4 *Availability*. Availability is the percentage of time over any 168-hour interval that the predicted 95 per cent positioning error (due to space and control segment errors) is less than its threshold, for any point within the coverage area. It is based on a 15-metre horizontal 95 per cent threshold and a 22-metre vertical 95 per cent threshold; using a representative receiver and operating within the coverage area over any 168-hour interval. The service availability assumes the worst combination of two out-of-service satellites.

4.1.4.4.1 *Satellite/constellation availability*. At least 24 satellites in the 27 nominal plane/slot positions must be set healthy and must be transmitting a navigation signal with a 0.998 probability (yearly averaged). At least 21 satellites in the 27 nominal plane/slot positions must be set healthy and must be transmitting a navigation signal with a 0.99999 probability (yearly averaged).

4.1.4.5 *Major service failure*

4.1.4.5.1 The single satellite major service failure is the condition that the SIS ranging error (excluding atmospheric and receiver errors) of any satellite exceeds the not-to-exceed (NTE) tolerance without an alert to users. For B1I signals, the NTE tolerance is defined to be 4.42 times the upper bound of the URA range corresponding to the URA index (URAI) value being broadcast in D1 navigation messages, as described in Appendix B, section 3.1.4.1.3.1.2. For B1C and B2a signals, the NTE tolerance is defined to be 4.42 times the signal-in-space accuracy (SISA) value calculated as described in Appendix B, section 3.1.4.2.5. The P_{sat} of 1×10^{-5} in Chapter 3, 3.7.3.1.4.4.1 corresponds to a maximum of three major service failures for each BDS OS signal per year assuming a maximum constellation of 30 satellites. The Mean Time to Notify (MTN) is 60 minutes.

4.1.4.5.2 The common-cause major service failure is a condition that the BDS OS SIS user range error of two or more satellites will exceed the NTE tolerance due to a common fault without an alert received at the user receiver antenna. For B1I signals, the NTE tolerance is defined to be 4.42 times the upper bound of the URA range corresponding to the URA index (URAI) value being broadcast in D1 navigation messages, as described in Appendix B, section 3.1.4.1.3.1.2. For B1C and B2a signals, the NTE tolerance is defined to be 4.42 times the SISA value calculated as described in Appendix B, section 3.1.4.2.5. The P_{const} of 6×10^{-5} in Chapter 3, 3.7.3.1.4.4.2 corresponds to a maximum of 0.5 commonly caused major service failures for the entire constellation per year. The MTN is 60 minutes.

4.1.4.6 *Continuity*. Continuity for a healthy BDS satellite is the probability that the BDS OS SIS will continue to be healthy without unscheduled interruption over a specified time interval. Scheduled interruptions, which are announced at least 24 hours in advance, do not contribute to a loss of continuity.

4.1.4.7 *Coverage*. The BDS OS supports the terrestrial coverage area which is from the surface of the earth up to an altitude of 1 000 km.

4.1.4.8 *BDS time*. The time reference for the BDS uses the BeiDou Navigation Satellite System Time (BDT), as described in Appendix B, 3.1.4.4.

4.1.4.9 *BDS coordinate system*. BDS uses the BeiDou Coordinate System (BDCS).

4.1.4.9.1 *BDSCS origin, axis and scale*. The origin is located at the earth's centre of mass; the Z-axis is the direction of the IERS (International Earth Rotation and Reference System Service) Reference Pole (IRP); the

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 55

X-axis is the intersection of IERS Reference Meridian (IRM) and the plane passing through the origin and normal to the Z-axis; the Y-axis, together with the Z-axis and the X-axis, constitute a right-handed orthogonal coordinate system. The length unit is the international system of units (SI) metre.

4.1.4.9.2 *BDCS Ellipsoid*. The geometric centre of the BDCS Ellipsoid coincides with the earth's centre of mass, and the rotation axis of the BDCS Ellipsoid is the Z-axis. The parameters of BDCS Ellipsoid are defined as:

Semi-major axis:	$a = 6\,378\,137.0\text{ m}$
Geocentric gravitational constant (mass of the earth's atmosphere included):	$\mu = 3.986004418 \times 10^{14}\text{ m}^3/\text{s}^2$
Flattening:	$f = 1/298.257222101$
Earth rotation rate:	$\dot{\Omega}_e = 7.2921150 \times 10^{-5}\text{ rad/s}$

4.3 Dilution of precision

Dilution of precision (DOP) factors express how ranging accuracy is scaled by a geometry effect to yield position accuracy. The optimal geometry (i.e. the lowest DOP values) for four satellites is achieved when three satellites are equally spaced on the horizon, at minimum elevation angle, and one satellite is directly overhead. The geometry can be said to “dilute” the range domain accuracy by the DOP factor.

4.4 GNSS antenna and receiver

4.4.1 The antenna specifications in Appendix B, 3.8.3.1, determine the axial ratio performance of the antennas. The specifications for the single-frequency only antennas do not control the antenna axial ratio except at boresight.

4.4.2 Linear polarization should be assumed for the airborne antenna for SBAS GEO signals received at low-elevation angles. For instance, when receiving an SBAS GEO signal that needs to be provided at a minimum elevation angle of 5 degrees, single-frequency antennas should be presumed to be linearly polarized with -2.5 dBil (-5.5 dBic) gain. This should be taken into account in the SBAS GEO satellite link budget in order to ensure that the minimum received RF signal at the antenna port meets the requirements of Chapter 3, 3.7.3.4. 5.3.2 and 3.7.3.4.6.3.

4.4.2 3 The failures caused by the receiver can have two consequences on navigation system performance which are the interruption of the information provided to the user or the output of misleading information. Neither of these events are accounted for in the signal-in-space requirement.

4.4.4 3 The nominal error of the GNSS aircraft element is determined by receiver noise, interference, and multipath and tropospheric model residual errors. Specific receiver noise requirements for both the SBAS airborne receiver and the GBAS airborne receiver include the effect of any interference below the protection mask specified in Appendix B, 3.7. The required performance has been demonstrated by receivers that apply narrow correlator spacing or code smoothing techniques.

4.4.5 The method for the search of the in-band, near-band and out-of-band maximum non-aeronautical interference tolerable power consists, for each interference bandwidth BW_i , in computing the largest value of the Spectral Separation Coefficient (SSC) for all PRNs and for all central frequencies $f_{c_i} = f_{CL1orL5} \pm \max(BW_{GNSS}/2, BW_i/2)$, where $BW_{GNSS} = 20\text{ MHz}$. For all GNSS signals' modulations (BPSK and MBOC) considered in the SARPs, this process results in an in-band, near-band maximum tolerable power monotonously increasing with BW_i . The out-of-band maximum tolerable power is evaluated for $BW_i = 1\text{ kHz}$.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 56

4.4.6 Following Note 5 in Table B-87 of Appendix B, Table B-87 does not describe non-aeronautical pulsed interferences in the environment to be considered for the L5 channel in an L1/L5 receiver as their impact is negligible compared to DME/TACAN and JTIDS/MIDS impact considered in the environment.

5. Aircraft-based Augmentation System (ABAS)

5.1 ABAS augments and/or integrates the information obtained from GNSS elements with information available on board the aircraft in order to ensure operation according to the values specified in Chapter 3, 3.7.2.4.

5.2 ABAS includes processing schemes that provide:

- a) integrity monitoring for the position solution using redundant information (e.g. multiple range measurements). The monitoring scheme generally consists of two functions: fault detection and fault exclusion. The goal of fault detection is to detect the presence of a positioning failure. Upon detection, proper fault exclusion determines and excludes the source of the failure (without necessarily identifying the individual source causing the problem), thereby allowing GNSS navigation to continue without interruption. There are two general classes of integrity monitoring: receiver autonomous integrity monitoring (RAIM), which uses GNSS information exclusively, and aircraft autonomous integrity monitoring (AAIM), which uses information from additional on-board sensors (e.g. barometric altimeter, clock and inertial navigation system (INS));
- b) continuity aiding for the position solution using information of alternative sources, such as INS, barometric altimetry and external clocks;
- c) availability aiding for the position solution (analogous to the continuity aiding); and
- d) accuracy aiding through filtering techniques and/or estimation of remaining errors in determined ranges.

5.3 Non-GNSS information can be integrated with GNSS information in two ways:

- a) integrated within the GNSS solution algorithm (an example is the modelling of altimetry data as an additional satellite measurement); and
- b) external to the basic GNSS position calculation (an example is a comparison of the altimetry data for consistency with the vertical GNSS solution with a flag raised whenever the comparison fails).

5.4 Each scheme has specific advantages and disadvantages, and it is not possible to present a description of all potential integration options with specific numerical values of the achieved performance. The same applies to the situation when several GNSS elements are combined (e.g. GPS and GLONASS).

6. Satellite-Based Augmentation System (SBAS)

6.1 SBAS may provide an L1 SBAS service augmenting GPS and/or GLONASS constellations, a dual-frequency, multi-constellation (DFMC) SBAS service augmenting one or more (up to four) constellations, or both services. The L1 SBAS service uses the L1 message data to support single-frequency service. The DFMC SBAS service uses the L5 message data to support DFMC SBAS service. The SBAS messages and data content of the L1 SBAS and DFMC SBAS services are independent and users can only apply the data from the data channel associated with the specific service. In addition, when the SBAS supports ranging, the SBAS satellite may be used as a single-frequency ranging source on L1 using the L1 data, or a dual-frequency ranging source combining both L1 and L5 pseudo-ranges using the L5 data. An SBAS is made up of three distinct elements:

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 57

- a) the ground infrastructure;
- b) the SBAS satellites; and
- c) the SBAS airborne receiver.

6.1.1 The ground infrastructure includes the monitoring and processing stations that receive the data from the navigation satellites and compute integrity, corrections and ranging data which form the SBAS signal-in-space. The SBAS satellites relay the data relayed from the ground infrastructure to the SBAS airborne receivers that determine position and time information using core satellite constellation(s) and SBAS satellites. The SBAS airborne receivers acquire the ranging and correction data and apply these data to determine the integrity and improve the accuracy of the derived position.

6.1.2 The SBAS ground network measures the pseudo-range between the ranging source and an SBAS receiver at the known locations and provides separate corrections for ranging source ephemeris errors, clock errors and, in addition for the L1 SBAS service, ionospheric delays and errors. The user applies a tropospheric delay model.

6.1.3 The ranging source ephemeris error and slow-moving clock error are the primary basis for the corrections provided in DFMC SBAS service and provided in the long-term correction in L1 SBAS. The ranging source clock error is adjusted for the long-term correction and tropospheric error and is the primary basis for the fast correction provided in L1 SBAS service. The ionospheric errors among many ranging sources are combined into vertical ionospheric errors at predetermined ionospheric grid points. These errors are the primary basis for ionospheric corrections provided in L1 SBAS service. No fast corrections are provided in DFMC SBAS service as a result of the slow clock drift performance of GNSS core constellations. No ionospheric corrections are provided in DFMC SBAS service as DFMC SBAS corrections are provided for ranging derived from the ionosphere-free combination of satellite signals, which removes almost all ionospheric delay from the ranging measurements.

6.2 SBAS coverage area and service areas

6.2.1 It is important to distinguish between the coverage area and service areas for an SBAS. A coverage area typically corresponds to the union of SBAS satellite footprint areas and comprises one or more service areas. Service areas are declared by SBAS service providers or by the State or group of States managing the SBAS, for the typical operations defined in Table 3.7.2.4-1 (e.g. En-route, APV-I, Category I) where the corresponding accuracy, integrity and continuity requirements are met with a certain availability (e.g. 99 per cent). Some SBAS service providers publish service areas of their systems e.g. WAAS Performance standard, EGNOS Service Definition Document and AIPs). The service area for En-route may be ~~wider~~ larger than the service area for APV-I. DFMC SBAS can provide service areas that can be larger than service areas provided by L1 SBAS for the same service levels. For the GNSS receiver, the SIS is usable whenever the protection levels are lower than the alert limits for the intended operation ($VPL < VAL$ and $HPL < HAL$), irrespective of whether or not the GNSS receiver is inside the corresponding service area defined by the SBAS service provider.

6.2.1.1 SBAS systems support operations based on some or all of the SBAS functions defined in Chapter 3, 3.7.3.4.2. These functions can be related to the operations that are supported as follows:

- a) *Ranging*: SBAS can provides a single-frequency ranging source on L1. L1 ranging can be used in the SBAS solution or for other augmentation(s) (ABAS, GBAS or other SBAS); SBAS can provide a dual-frequency ranging source using L1 and L5 frequencies suitable for a DFMC SBAS position derived from the broadcasting SBAS system.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 58

- b) Satellite status and basic differential corrections: L1 SBAS provides en-route, terminal, and non-precision approach service. Different operations (e.g. performance-based navigation operations) may be supported in different service areas;
- c) Precise differential corrections: L1 SBAS provides APV and precision approach service (i.e. APV-I, APV-II and Category I precision approach may be supported in different service areas).
- d) *Ionosphere-free differential correction*: DFMC SBAS provides en-route, terminal, non-precision approach, APV and precision approach service (i.e. APV-I and Category I precision approach). Different operations (e.g. PBN operations) may be supported in different service areas.

6.2.2 Satellite-based augmentation services are provided by the Wide Area Augmentation System (WAAS) (North America), the European Geostationary Navigation Overlay Service (EGNOS) (Europe and Africa), the Michibiki Satellite-based Augmentation Service (MSAS) (Japan) and the GPS-aided Geo-augmented Navigation (GAGAN) (India). The System for Differential Correction and Monitoring (SDCM) (Russia), the BeiDou Satellite-based Augmentation System (BDSBAS) (China), the Korea Augmentation Satellite System (KASS) (Republic of Korea), the Augmented Navigation for Africa (ANGA) (ASECNA) and the Southern Positioning Augmentation Network (SouthPAN) (Australia and New Zealand) are also under development to provide these services.

6.2.3 An SBAS may provide accurate and reliable service outside the defined service area(s). The ranging, satellite status basic differential corrections and ionosphere-free differential correction functions are usable throughout the entire coverage area. The performance of these functions may be technically adequate to support en-route, terminal and non-precision approach operations by providing monitoring and integrity data for core satellite constellations and/or SBAS satellites. L1 SBAS mitigates errors which cannot be monitored by its ground network through message Types 27 or message Type 28. DFMC SBAS mitigates errors that cannot be monitored by its ground network through message Type 32.

6.2.4. Air navigation service Providers shall ensure that operations of SBAS in Bhutan airspace shall meet the requirements of Chapter 3, 3.7.2.4, and that appropriate operational status reporting and NOTAMs are provided

6.2.5 Before approving SBAS-based operations, a BCAA shall determine that the proposed operations are adequately supported by one or more SBASs. This determination should focus on the practicality of using SBAS signals, taking into account the relative location of the SBAS ground network. This could involve working with the State(s) or organization(s) responsible for operating the SBASs. For an airspace located relatively far from an SBAS ground network, the number of visible satellites for which that SBAS provides status and basic corrections would be reduced. Since L1 SBAS receivers are able to use data from two SBASs simultaneously, and to use autonomous fault detection and exclusion, when necessary, availability may still be sufficient for approval of operations. Unlike the L1 SBAS service that can only provide ionospheric delay estimate near the SBAS reference network, the ionosphere-free differential corrections will provide a valid solution in airspace located relatively far from the SBAS reference network. In most cases, there will be overlap of DFMC services from neighbouring SBAS systems and users will be able to transition directly from one SBAS system to another. There is no benefit from the combination of ranging sources corrected by two or more SBAS services, but there would be additional error bounding to account for potential differences among SBAS services. Therefore, the use of multiple SBAS is not permitted when using dual-frequency service.

6.2.6 Before publishing procedures based on SBAS signals, ANSP shall provide a status monitoring and NOTAM system. To determine the effect of a system element failure on service, a mathematical service volume model is to be used. ANSP can either obtain the model from the SBAS operator or develop its own model. Using the current and forecast status data of the basic system elements, and the locations where the state has approved operations, the model would identify airspace and airports where service outages are expected, and it could be

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

used to originate NOTAMs. The system element status data (current and forecast) required for the model could be obtained via a bilateral arrangement with the SBAS service provider, or via connection to a real time “broadcast” of the data if the SBAS service provider chooses to provide data in this way.

6.2.7 Participating States or regions will coordinate through ICAO to ensure that SBAS provides seamless global coverage, taking into account. Recommendation 2.2/2 b) of the Thirteenth Air Navigation Conference, which calls for States to avoid, in principle, prohibiting the use of available GNSS elements if they perform according to ICAO SARPs and can meet all safety and regulatory requirements for the intended operations.

6.2.8 As the SBAS satellite coverages (footprints) overlap, it will be necessary for SBAS equipment to handle selection and transition mechanisms among the SBASs. As a minimum, the SBAS airborne receivers must be able to operate within the coverage of any SBAS. It is possible for an L1-only SBAS provider to monitor and send integrity and correction data for a geostationary orbit satellite that belongs to another SBAS service provider. For L1 SBAS, augmenting ranging SBAS satellites can improve availability by adding ranging sources for user receivers that can track additional SBAS satellites. This improvement does not require any interconnection between SBAS systems and should be accomplished by all SBAS service providers. For DFMC SBAS, the ranging signal from the SBAS PRN in use may be used. Ranging signal from other SBAS satellite(s) from the same provider may be used with Type 32 message augmentation. Ranging signal from other SBAS providers cannot be used.

6.2.9 Other levels of integration can be implemented using a unique connection between the SBAS networks (e.g. separate satellite communication). In this case, SBASs can exchange either raw satellite measurements from one or more reference stations or processed data (corrections or integrity data) from their master stations. This information can be used to improve system robustness and accuracy through data averaging, or integrity through a cross check mechanism. Availability will also be improved within the service areas, and the technical performance will meet the GNSS SARPs throughout the entire coverage (i.e. monitoring of satellites ephemeris would be improved). Finally, SBAS control and status data could be exchanged to improve system maintenance.

6.3 Integrity

6.3.1 The provisions for integrity are complex, as some attributes are determined within the SBAS ground network and transmitted in the signal-in-space, while other attributes are determined within the SBAS equipment on the aircraft. For the satellite status ~~and~~, basic corrections functions and ionosphere-free differential corrections functions, an error uncertainty for the ephemeris and clock corrections is determined by the SBAS ground network. This uncertainty is modelled by the variance of a zero-mean, normal distribution that describes the user differential range error (UDRE) or dual-frequency range error (DFRE) for each ranging source after application of fast (L1 SBAS) and long-term (L1 and DFMC SBAS) corrections and excluding atmospheric effects and receiver errors.

6.3.2 For the precise differential function, an error uncertainty for the ionospheric correction is determined. This uncertainty is modeled by the variance of a zero-mean, normal distribution that describes the L1 residual user ionospheric range error (UIRE) for each ranging source after application of ionospheric corrections. This variance is determined from an ionospheric model using the broadcast grid ionospheric vertical error (GIVE).

6.3.3 There is a finite probability that an SBAS receiver would not receive an SBAS message. In order to continue navigation in that case, the SBAS broadcasts degradation parameters in the signal-in-space. These parameters are used in a number of mathematical models that characterize the additional residual error from basic precise and ionosphere-free differential corrections induced by using old but active data. These models are used to modify the UDRE/DFRE variance and the UIRE variance as appropriate.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 60

6.3.4 The individual error uncertainties described above are used by the receiver to compute an error model of the navigation solution. This is done by projecting the pseudo-range error models to the position domain. The horizontal protection level (HPL) provides a bound on the horizontal position error with a probability derived from the integrity requirement. Similarly, the vertical protection level (VPL) provides a bound on the vertical position. If the computed HPL exceeds the horizontal alert limit (HAL) for a particular operation, SBAS integrity is not adequate to support that operation. The same is true for precision approach and APV operations, if the VPL exceeds the vertical alert limit (VAL).

6.3.5 One of the most challenging tasks for an SBAS provider is to determine UDRE/GIVE or DFRE variances so that the protection level integrity requirements are met without having an impact on availability. The performance of an individual SBAS depends on the network configuration, geographical extent and density, the type and quality of measurements used and the algorithms used to process the data. General methods for determining the model variance are described in section 14.

6.3.6 Residual clock and ephemeris error (σ_{UDRE}). The residual clock error is well characterized by a zero-mean, normal distribution since there are many receivers that contribute to this error. The residual ephemeris error depends upon the user location. For the precise differential function, the SBAS provider will ensure that the residual error for all users within a defined service area is reflected in the σ_{UDRE} . For the basic differential function, the residual ephemeris error should be evaluated and may be determined to be negligible.

6.3.7 *Ionosphere-free residual clock and ephemeris error (σ_{DFRE})*. The residual clock error is well characterized by a zero-mean, normal distribution since there are many receivers that contribute to this error. The residual ephemeris error depends upon the user location. For the ionosphere-free differential correction function, the SBAS provider will ensure that the residual error for all users within a coverage area is reflected in the σ_{DFRE} . The residual error needs to account for the increased noise in the ionosphere-189 free dual-frequency combination.

6.3.8 Vertical ionospheric error (σ_{GIVE}). The residual ionospheric error is well represented by a zero-mean, normal distribution since there are many receivers that contribute to the ionospheric estimate. Errors come from the measurement noise, the ionospheric model and the spatial decorrelation of the ionosphere. The position error caused by ionospheric error is mitigated by the positive correlation of the ionosphere itself. In addition, the residual ionospheric error distribution has truncated tails, i.e. the ionosphere cannot create a negative delay, and has a maximum delay.

6.3.9 *Aircraft element errors*. The combined multipath and receiver contribution is bounded as described in section 14. This error can be divided into multipath and receiver contribution as defined in Appendix B, 3.6.5.5.1, and the standard model for multipath described in Appendix B, 3.6.5.5.1.1.2 may be used. The receiver contribution can be taken from the accuracy requirement (Appendix B, 3.5.8.2, 3.5.8.4.1 and 3.5.15.3.2) and extrapolated to typical signal conditions. Specifically, the aircraft can be assumed to have $\sigma_{2air} = \sigma_{2receiver} + \sigma_{2multipath}$, where it is assumed that $\sigma_{receiver}$ is defined by the RMS_{pr_air} specified for GBAS Airborne Accuracy Designator A equipment, and $\sigma_{multipath}$ is defined in Appendix B, 3.6.5.5.1 for L1 SBAS equipment and 3.5.15.3.4.1 for DFMC SBAS equipment. The aircraft contribution to multipath includes the effects of reflections from the aircraft itself. Multipath errors resulting from reflections from other objects are not included. If experience indicates that these errors are not negligible, they must be accounted for operationally. The standard multipath model in Appendix B, 3.5.15.3.4.1 accounts for multipath error in the ionosphere-free combination.

6.3.10 Tropospheric error. The receiver must use a model to correct for tropospheric effects. The residual error of the model is constrained by the maximum bias and variance defined in Appendix B, 3.5.8.4.2 and 3.5.8.4.3. The effects of this mean must be accounted for by the ground subsystem. The airborne user applies a specified model for the residual tropospheric error (σ_{tropo}).

6.4 RF Characteristics

6.4.1 **Minimum SBAS L1 GEO signal power level.** The minimum aircraft equipment (e.g. RTCA/DO-229D with Change 1) is required to operate with a minimum signal strength of -164 dBW at the antenna port in the presence of non-RNSS interference (Appendix B, 3.7) and an aggregate RNSS noise density of -172.8 dBm/Hz. In the presence of interference, receivers may not have reliable tracking performance for a signal strength at the antenna port below -164 dBW (e.g. with GEO satellites placed in orbit prior to 2014). A GEO that delivers a signal power below -164 dBW at the receiving antenna port at 5-degree elevation on the ground can be used to ensure signal tracking in a service area contained in a coverage area defined by a minimum elevation angle that is greater than 5 degrees (e.g. 10 degrees). In this case, advantage is taken from the gain characteristic of the minimum standard (e.g. RTCA/DO-301) antenna to perform a trade-off between the GEO signal power and the size of the service area in which a trackable signal needs to be ensured. When planning for the introduction of new operations based on SBAS, NASPs are expected to conduct an assessment of the signal power level as compared to the level interference from RNSS and non-RNSS sources. If the outcome of this analysis indicates that the level of interference is adequate to operate, then operations can be authorized.

6.4.2 *Minimum SBAS L5 signal power level.* The minimum aircraft equipment is required to operate with a minimum signal strength of -158 dBW at the antenna port in the presence of non-RNSS interference (Appendix B, 3.7) and an aggregate RNSS noise density of -171.4 dBm/Hz. An SBAS satellite that delivers a signal power below -158 dBW at the receiving antenna port at 5-degree elevation on the ground can be used to ensure signal tracking in a service area contained in a coverage area defined by a minimum elevation angle that is greater than 5 degrees (e.g. 10 degrees). In this case, advantage is taken from the gain characteristic of the standard antenna to perform a trade-off between the SBAS satellite power and the size of the service area in which a trackable signal needs to be ensured.

6.4.3 *SBAS network time.* SBAS network time is a time reference maintained by SBAS for the purpose of defining corrections. When using corrections, the user's solution for time is relative to the SBAS network time rather than core satellite constellation system time, if corrections are not applied, the position solution will be relative to a composite core satellite constellation/SBAS network time depending on the satellites used and the resulting accuracy will be affected by the difference among them. Mix of uncorrected and SBAS corrected measurement is not allowed in DFMC SBAS. L1 SBAS and DFMC SBAS services are independent. The SBAS network time used for L1 SBAS and that used for DFMC SBAS may be different. In DFMC SBAS, a time reference identifier parameter is broadcast in Type 37 message to inform DFMC user about the core constellation time reference used to steer the SBAS network time in DFMC SBAS (see Chapter 3, 3.7.3.4.7.2 which specifies the maximum time difference between SNT and core constellation reference time). It refers to the time reference of a GNSS constellation, which will be assumed to be the constellation of reference when computing SBAS user position and estimating time offset for other constellation augmented by the SBAS system. 6.4.3 SBAS convolutional encoding. Information on the convolutional coding and decoding of SBAS messages can be found in RTCA/DO-229D with Change 1, Appendix A.

6.4.4 *SBAS convolutional and bi-binary encoding.* Information on the convolutional coding and decoding of L1 SBAS messages can be found in RTCA/DO-229D with Change 1, Appendix A. Information on the convolutional coding and decoding of DFMC SBAS messages can be found in EUROCAE/ED-259, Appendix A. The SBAS L5 signals use bi-binary (Manchester) encoding (see section 1). SBAS L5 signals without bi-binary encoding are suitable for testing and validation purposes only. Figure D-19 shows the convention of the bi-binary encoding, where a "0" is expressed by a low-to-high transition ("0" during the first half of the bit period and "1" during the second half) and where a "1" is expressed by a high-to-low transition ("1" during the first half of the bit period and "0" during the second half).

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

6.4.5 Message timing. The users' convolutional decoders will introduce a fixed delay that depends on their respective algorithms (usually 5 constraint lengths, or 35 bits), for which they must compensate to determine SBAS network time (SNT) from the received signal.

6.4.6 *SBAS signal characteristics.* Differences between the relative phase and group delay characteristics of SBAS signals, as compared to GPS signals, can create a relative range bias error in the receiver tracking algorithms. The SBAS service provider is expected to account for this error, as it affects receivers with tracking characteristics within the tracking constraints in Attachment D, 8.11 and Appendix B, 3.5.15.1.1.3. For GEOs supporting L1 SBAS ranging for which the on-board RF filter characteristics have been published in RTCA/DO-229D with Change 1, Appendix T, the SBAS service providers are expected to ensure that the UDREs bound the residual errors including the maximum range bias errors specified in RTCA/DO-229D with Change 1. For other SBAS satellites supporting L1 SBAS ranging or DFMC SBAS ranging, the SBAS service providers are expected to work with equipment manufacturers in order to determine, through analysis, the maximum range bias errors that can be expected from existing receivers when they process these specific satellites. This effect can be minimized by ensuring that the satellites have a wide transmission bandwidth and small group delay across the pass-band. Additionally, the DFMC SBAS tracking error in Appendix B, 3.5.15.4.1 is developed with the presumption that the SBAS L1 signal supporting DFMC SBAS ranging is a wideband signal. SBAS service providers are expected to ensure that the DFREs bound the residual errors including tracking bias errors for the DFMC SBAS ranging signals.

6.4.7 *SBAS pseudo-random noise (PRN) codes.* RTCA/DO-229D with Change 1, Appendix A, provides two methods for SBAS L1 PRN code generation. EUROCAE/ED-259, Appendix A, provides a method for SBAS L5 PRN code generation.

6.4.8 *SBAS L5 carrier phase noise.* A practical way to comply with the SBAS L5 code carrier noise requirement would be to comply with the following table specification:

Table D-3. L5 carrier phase noise

<i>Frequency offset from L5 carrier (Hz)</i>	<i>Phase noise relative to the carrier (dBc/Hz)</i>
0	0
1	-19.5
5	-47.5
10	-52.5
10^2	-66.5
10^3	-74.5
10^4	-85.5
10^5	-90.5
3×10^5	-90.5
Greater than 10^6	-92.5

6.4.9 *Cross-correlation loss.* Cross-correlation loss is defined as the ratio of the following two correlation outputs: (1) the actual received signal correlated against a perfect unfiltered reference signal; and (2) a perfect unfiltered signal normalized to the same total power as the signal in case (1), correlated against a perfect unfiltered reference signal. The correlation loss can be calculated as indicated in the equation below:

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 63

$$-20 \text{ Log}_{10} \left[\frac{C_{XY}}{\sqrt{C_{XX}} \sqrt{C_{YY}}} \right] < 1 \text{ dB}$$

where “C_{XX}” is the value resulting from correlation of the unfiltered reference signal with itself, “C_{YY}” is the value resulting from correlation of the actual received signal with itself, and “C_{XY}” is the value resulting from correlation of the actual received signal with the unfiltered reference signal when these two signals are optimally aligned for maximal cross correlation. The bracketed term above is the correlation coefficient between the actual received signal and the unfiltered reference signal.

6.5 Data characteristics on SBAS L1 signal

6.5.1 SBAS messages. Due to the limited bandwidth, SBAS L1 signal data is encoded in messages that are designed to minimize the required data throughput. RTCA/DO-229D with Change 1, Appendix A, provides detailed specifications for SBAS messages.

6.5.2 Data broadcast intervals. The maximum broadcast intervals between L1 SBAS messages are specified in Appendix B, Table B-54. These intervals are such that a user entering the L1 SBAS service broadcast area is able to output a corrected position along with SBAS-provided integrity information in a reasonable time. For en-route, terminal and NPA operations, all needed data will be received within 2 minutes, whereas for precision approach operations, it will take a maximum of 5 minutes. The maximum intervals between broadcasts do not warrant a particular level of accuracy performance as defined in Chapter 3, Table 3.7.2.4-1. In order to ensure a given accuracy performance, each service provider will adopt a set of broadcast intervals taking into account different parameters such as the type of constellations (e.g. GPS with SA, GPS without SA) or the ionospheric activity.

6.5.3 Time-to-alert. Figure D-2 provides explanatory material for the allocation of the total time-to-alert defined in Chapter 3, Table 3.7.2.4-1. The time-to-alert requirements in Appendix B, 3.5.7.3.1, 3.5.7.4.1 and 3.5.7.5.1 (corresponding to the GNSS satellite status, basic differential correction and precise differential correction functions, respectively) include both the ground and space allocations shown in Figure D-2.

6.5.4 Tropospheric function. Because tropospheric refraction is a local phenomenon, users will compute their own tropospheric delay corrections. A tropospheric delay estimate for precision approach is described in RTCA/DO-229D with Change 1, although other models can be used.

6.5.5 Multipath considerations. Multipath is one of the largest contributors to positioning errors for **L1** SBAS affecting both ground and airborne elements. For SBAS ground elements, emphasis should be placed on reducing or mitigating the effects of multipath as much as possible so that the signal-in-space uncertainties will be small. Many mitigation techniques have been studied from both theoretical and experimental perspectives. The best approach for implementing SBAS reference stations with minimal multipath errors is to:

- a) ensure that an antenna with multipath reduction features is chosen;
- b) consider the use of ground plane techniques;
- c) ensure that the antenna is placed in a location with low multipath effects; and
- d) use multipath-reducing receiver hardware and processing techniques.

6.5.6 GLONASS issue of data. Since the existing GLONASS design does not provide a uniquely defined identifier for sets of ephemeris and clock data, L1 SBAS will use a specific mechanism to avoid any ambiguity in the application of the broadcast corrections. This mechanism is explained in Figure D-3. The definitions of

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

the latency time and validity interval along with the associated coding requirements can be found in Appendix B, section 3.5.4. The user can apply the long-term corrections received only if the set of GLONASS ephemeris and clock data used on board have been received within the validity interval.

6.6 SBAS final approach segment (FAS) data block

6.6.1 The SBAS final approach segment (FAS) data block for a particular approach procedure is as shown in Appendix B, 3.5.8.4.2.6.1 and Table B-57A, with additional description of fields used by DFMC SBAS user equipment in Appendix B, 3.5.15.3.5. The format is the same as the GBAS FAS data block defined in Appendix B, 3.6.4.5.1 and Table B-66, with the following exceptions. The SBAS FAS data block also contains the HAL and VAL to be used for the approach procedure as described in 6.3.4. SBAS user equipment interprets certain fields differently from GBAS user equipment and DFMC SBAS user equipment uses two fields not used by L1 SBAS user equipment. The new fields have been defined such that existing FAS data blocks designed for the L1 SBAS service are compatible for use with DFMC SBAS user equipment. FAS data blocks that have APD codings other than 0 are only for use by and should only be installed on aircraft with DFMC SBAS user equipment..

6.6.2 FAS data blocks for SBAS and some GBAS approaches are held within a common on-board database supporting both SBAS and GBAS. Within this database, channel assignments must be unique for each approach and coordinated with civil authorities. ANSPs are responsible for providing the FAS data for incorporation into the database.

6.6.3 An example of the coding of FAS data block for SBAS is provided in Table D-1. This example illustrates the coding of the various application parameters, including the cyclic redundancy check (CRC). The engineering values for the message parameters in the table illustrate the message coding process

6.6.4 DFMC SBAS user equipment uses the operation type field from the FAS data block to determine the required SBAS service provider identifier (SPID) for the approach. The DFMC SBAS service broadcasts a 5-bit SPID while the FAS data block only supports a 4-bit SPID. To differentiate the additional 16 SPID values, the DFMC SBAS user equipment looks for the operation type field. User equipment that receives an operation type of 0 or does not read the operation type field will interpret the SPID as published with values between 0 and 15. User equipment that receives an operation type of 8 will add 16 to the value of the SPID from the FAS data block, resulting in a range from 16 to 31. This expanded range can only be broadcast on the DFMC SBAS service and is intended for use by SBAS systems that only provide a DFMC SBAS service.

The FAS CRC value is displayed in the order r₂₅-r₁₃, r₁₇-r₁₄, r₉-r₁₆, r₁-r₈ where r_i is the ith coefficient of the remainder R(x) as defined in Appendix B, 3.9. D_N : raw data value, D_{CONV} : converted data value according to coding rules, D_{OUT} : coded data value. 									

6.6.5 DFMC SBAS user equipment uses the approach performance designator (APD) field to identify which of the SBAS services provide adequate performance to support the procedure identified in the FAS data block. The service

modes are the L1 SBAS service, the DFMC SBAS when one or more augmented constellations are usable, and the DFMC SBAS service when two or more augmented constellations are usable. Constellations are usable when the SBAS provides augmentation and the user equipment can use the augmentation. For procedures using APV performance level, the user equipment can check the computed protection level(s) against the associated alert limit(s) to determine suitability of the navigation. For procedures using the Category 1 performance level, the integrity referred to in Chapter 3, Table 3.7.2.4.-1, Note 2 requires a system-specific safety analysis when the VAL is set to be greater than 10 m. This includes a performance assessment that the SBAS service provider makes, which the ANSP can use to support the decision on the APD coding for published procedures. Since the DFMC SBAS service will have a significantly larger service volume than the L1 SBAS service, ANSPs will be able to publish approach procedures based on DFMC SBAS services that an associated L1 SBAS service cannot fully support. In some circumstances, the L1 SBAS service might not meet the availability or continuity for the approach but would otherwise meet the performance requirements and could be used, if available. ANSPs can then publish the procedure with APD codings of 5 or 6 based on the L1 SBAS service performance provided by the SBAS service provider. In some circumstances, when the L1 SBAS service does not meet the criteria in 3.3.9 or when the ANSP determines that the L1 SBAS service is not suitable for use, ANSPs can then publish procedures with APD codings of 1 or 2. The table below provides an indication of when the different APD codings are appropriate. ANSPs code DFMC SBAS procedure with an APD of 1 or 2 when there is no L1 SBAS service deemed to be available in support of flying the published approach.

0	<ul style="list-style-type: none"> Any procedure based on the APV performance level when the L1 SBAS service meets availability and continuity. Any procedure using the Category 1 performance level when the L1 SBAS service meets availability, continuity, and the system-specific safety assessment.
1	<ul style="list-style-type: none"> Any procedure based on the APV performance level when the ANSP wants to control the operation to DFMC mode only with at least one constellation. Any procedure based on the Category 1 performance level when the system specific safety assessment is met with the DFMC SBAS service with at least one constellation, but would not be met with an L1 SBAS service.
2	<ul style="list-style-type: none"> Any procedure based on the APV performance level when the ANSP wants to control the operation to DFMC mode only and two or more constellations are required to meet the availability and continuity requirements with the DFMC SBAS service. Any procedure based on the Category 1 performance level when the system specific safety assessment is met with the DFMC SBAS service but would not be met with an L1 SBAS service, and two or more constellations are required to meet the availability and continuity requirements with the DFMC SBAS service.
5	<ul style="list-style-type: none"> Any procedure based on the APV performance level when the L1 SBAS service is not expected to meet availability or continuity while DFMC SBAS service meets availability and continuity with at least one constellation. Any procedure based on the Category 1 performance level when both the DFMC and L1 SBAS services satisfy the system specific safety assessment, although the L1 SBAS service is not expected to meet availability and/or continuity.
6	<ul style="list-style-type: none"> Any procedure based on the APV performance level when availability and continuity are met only using a DFMC SBAS service augmenting more than one constellation. Neither single constellation DFMC SBAS, nor a L1 SBAS service are expected to meet availability and continuity. Any procedure based on the Category 1 performance level when availability and continuity are met only using a DFMC SBAS service augmenting more than one constellation. Neither single constellation DFMC SBAS, nor a L1 SBAS service are expected to meet availability and/or continuity, but all services meet the system specific safety assessment.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 68

6.6.6 User equipment not designed to process DFMC SBAS (e.g. compliant with RTCA/DO-229 standards) is not required to use the APD field (see Chapter 3, Appendix B, 3.5.8.4.2.6.1) whereas DFMC SBAS equipment uses this field. SBAS procedures developed for L1 SBAS service use an APD coded as 0. The 0 coding is therefore retained for procedures supported by both L1 SBAS and DFMC SBAS. SBAS user equipment not designed to process DFMC SBAS (e.g. compliant with RTCA/DO-229 standards) should only be used in combination with FAS data blocks with APD set to 0.

6.7 DFMC SBAS considerations

6.7.1 *Data broadcast intervals.* The maximum broadcast intervals between DFMC SBAS messages are specified in Appendix B, Table B-107. These intervals are such that a user entering the DMFC SBAS coverage area is able to output a corrected position along with SBAS-provided integrity information in a reasonable time. For en-route, terminal, NPA and precision approach operations, all needed data will be received within 3 minutes considering a maximum of 92 satellites set in the DFMC SBAS mask. The maximum intervals between broadcasts do not warrant a particular level of accuracy performance as defined in Chapter 3, Table 3.7.2.4-1. In order to ensure a given accuracy performance, each service provider will adopt a set of broadcast intervals taking into account different parameters such as the number of constellations augmented and the number of SBAS satellites used by the service provider.

6.7.2 DFMC SBAS mask

6.7.2.1 *SBAS mask parameters.* Appendix B, Table B-91, provides the mapping between the DFMC SBAS satellite mask and GNSS satellites. It was decided to define specific satellites per constellation that could be augmented in DFMC SBAS. It concerns the GPS PRN numbers 1 to 32 and 120 to 158 (SBAS PRN), GLONASS ID number 1 to 37, Galileo SVID 1 to 36 and BDS ranging code number 1 to 37. If any constellation broadcasts a signal from a satellite identified with a parameter exceeding the ranges specified, this satellite is not eligible for DFMC SBAS augmentation. DFMC SBAS mask broadcast in Type 31 message is independent from the L1 SBAS mask broadcast in Type 1 message even if both services are delivered by an SBAS provider.

6.7.2.2 *SBAS mask transition.* The Standard does not specify the means to conduct a mask transition, therefore SBAS providers might choose different mask transition strategies. The user requires a valid mask to decode the integrity messages sent every six seconds in the Type 34, 35 or 36 messages. The user needs to receive a valid integrity message at least every 12 seconds in order to continue vertical operations, since the integrity parameters time out after 12 seconds. The satellite mask message (Type 31) is valid for 360 seconds. Therefore, one method for mask transitions would be to start the transition with the broadcast of a new Type 31 message while continuing to reference the old Type 31 in the integrity messages. After the second (or third) transmission of the new Type 31, the SBAS would transition the integrity messages to use the new satellite mask message. Users should be able to receive the new satellite mask with two or three transmissions and, in the meantime, would continue to operate normally. Other satellite mask transition options could be used such as: broadcast two integrity messages per cycle, one using the old satellite mask and one using the new satellite mask. SBAS providers need to assess the impact on continuity of service associated with the selected mechanism for SBAS mask transition when the user misses some messages.

6.7.3 *DFMC SBAS almanac and ephemeris generation.* The DFMC SBAS ephemeris and almanac messages were designed to provide a set of Keplerian parameters. This design enables using SBAS satellites whose orbits are not geostationary ones. The DFMC SBAS ephemeris and almanac messages enable the broadcast of satellites in MEO, HEO, IGSO and GEO orbital position. For some special case orbits, like low-inclination (geostationary) orbits or circular, zero eccentricity orbits, some of the Keplerian parameters are not well defined and therefore are not unique. Valid sets of Keplerian parameters exist and the user will be able to properly determine the satellite position provided the SBAS creates a valid set of parameters. SBAS providers can set the problematic parameters to constant values and the resulting ephemeris or almanac fit will converge to a good solution. The SBAS

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 69

calculation removed the rate of right ascension of ascending node (RAAN) since the validity time of the ephemeris is short. Proper selection of the harmonic correction to argument of latitude can correct the error introduced by the removal of rate of RAAN for the geostationary satellite case. For the case of inclined orbits, the error is still not negligible and the compensation needs to include IDOT in combination with C_{us} and C_{uc} . These correction parameters were chosen in general as they allow for (roughly) along-track (C_{us} , C_{uc}) and cross-track (IDOT) corrections. Since the elimination of rate of RAAN is addressed by other parameters, a long parameter fitting interval may degrade accuracy of SBAS satellite position.

6.7.4 Integrity considerations

6.7.4.1 *General.* While the SBAS corrections remove the observable error, there remains some uncertainty on the residual error. The SBAS ground segment selects DFREs to broadcast to provide protection level bounding of the user’s residual position errors after the application of SBAS corrections. The SBAS ground segment should account for the growth of the uncertainty in the nominal error that occurs when the user applies any received augmentation data that remains valid (has not timed out). The SBAS ground segment can choose and broadcast the associated degradation parameters to help maintain this bounding. This ensures that alerts will not be necessary under normal conditions over the validity period of the corrections and the DFREs. As the uncertainty increases, the SBAS can increase the DFREs to maintain adequate bounding. Provided that the degradation parameters add sufficient bounding to meet the integrity requirements of Appendix B, 3.5.14.3, an increase in the current DFREs to cover nominal behaviour will not require an alert to protect users still applying older active values. As specified in Appendix B, 3.5.14.4.2, the SBAS system is required to monitor for satellite ranging faults and applicability of active SBAS data. During this monitoring, the SBAS is required to maintain integrity. For some monitored behaviours, like a clock run-off, if the errors are consistent with the SBAS system design and integrity analysis and the errors continue to be bounded by the active previously broadcast DFREs in combination with the degradation parameters, the SBAS should not broadcast an alert in order to maintain continuity. If the SBAS determines that old but active data with the degradations applied will not meet the integrity requirement, then the SBAS will broadcast an alert for that satellite. The alert could be in the form of larger DFREIs, up to and including the value indicating “Do Not Use in SBAS Mode”. For other monitored cases, like detection of abnormal signal quality, the SBAS may be better served to broadcast an alert for the satellite directly to “Do Not Use in SBAS Mode”.

6.7.4.2 *Mechanism.* There are several means to provide an alert. The alert sequence consists of a broadcast of at least four consecutive instances of data that will mitigate the misleading information. For individual satellites, it is often sufficient to broadcast larger DFREs to bound the error. This provides protection for all satellite data including that with longer time-out periods. Through this use of DFREs to alert, once the alerting condition has cleared, the nominal performance can be restored quickly by broadcasting nominal DFREs. The SBAS should expect that the user will miss messages and could be using any data that was previously broadcast that has not yet reached its time-out. When sending larger DFRE data to mitigate the misleading information, the SBAS sends the new DFRE in at least four consecutive messages. Since the DFRE terms are found in several different messages, it is possible to mix messages to achieve this repetition, such as four consecutive Type 32 messages or four consecutive Type 34/35/36 messages, or a combination of four consecutive Type 32 and integrity messages.

6.7.4.3 *Use of Type 0 message for alerts.* If necessary, to remove active data from the user receiver, SBAS can broadcast Type 0 messages. If the active data results in misleading information, the SBAS may use Type 0 message as an alert and send it in four consecutive messages. The reception of Type 0 messages will result in users dropping L5 data sent by the broadcasting satellite on the respective link. The use of Type 0 messages to alert individual satellites is generally not necessary as the use of larger DFREIs can provide for satellite alerts with less impact to the SBAS service.

6.7.4.4 *Missed messages and use of Type 0 messages.* Since the alert is required to be sent four times, a receiver might miss an alert if it misses four consecutive messages. For safety during approach operations, when the receiver misses four messages, it is required to invalidate all DFREIs/DFRECI (see Appendix B, 3.5.15.1.4.15).

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 70

The receiver could resume using correction data upon reception of an appropriate set of DFREIs with no other changes, as might occur with the reception of a Type 35 or Type 36 message. The SBAS should consider the possibility that the user receiver missed an alert sequence and should continue to broadcast DFREIs or DFRECI consistent with the alerted value for all correction data that remains valid. This is also true following broadcast of a Type 0 message. If the user misses four or more messages, the user will only time out the DFREIs/DFRECI and not remove other data. Therefore, the SBAS should consider how to resume nominal broadcast sequence following a Type 0 message alert sequence. The SBAS could continue to broadcast Type 0 messages or make impacted satellites unavailable until the misleading broadcast data has timed out. Transition from alerting through Type 0 messages to alerting through “Do Not Use for SBAS” may permit the receiver to use new SBAS data sooner.

6.7.5 Integrity data

6.7.5.1 Integrity messages. The DFMC SBAS concept defined three message types to provide integrity information with a repetition not to exceed six seconds. DFMC SBAS will broadcast integrity data for all satellites set in the satellite mask (Type 31 message), and can use any combination of these messages. The integrity messages are Types 34, 35 and 36. The Type 35 message provides DFREI information for the first 53 satellites in the Type 31 mask message and can be the sole message used when the SBAS augments 53 or fewer satellites. The Type 36 message is similar to the Type 35 message and is used together with the Type 35 message to broadcast DFREI information for satellites 54 to 92. Using a paired Type 35/36 message doubles the number of integrity messages being sent and might reduce the ability to send other information (e.g. correction information) more frequently compare to the minimum required. The Type 34 message is an option to provide integrity information for up to 92 satellites in a single SBAS message.

6.7.5.2 Use of the integrity message. The Type 34 message gives a means to provide integrity information for up to 92 satellites in a single message through the use of a 2-bit DFRE change indicator (DFRECI) instead of a 4-bit DFREI for each satellite. The Type 32 message provides the actual DFREI. For most operations, the DFREI will stay the same or only change by one increment during the time-out period of the DFREI. Therefore, the two-bit indicator has only four states indicating the following: 1) no change in DFREI, used to indicate that all broadcast, valid DFREIs remain valid; 2) increase the DFREI by one step (bump); 3) the Type 34 message will provide a new DFREI in one of seven slots allocated for DFREI updates in the message; or 4) indicate that the satellite is “Do Not Use for SBAS”. The user could apply the indicator to the last received DFREI that has not timed out. The SBAS system design accounts for the user missing prior broadcast DFREI and/or DFRECI values. The SBAS cannot expect the user to have the most recent DFREI and monitors all old but active data transmitted to comply with the integrity requirement in Appendix B, 3.5.14.3.1. The SBAS can provide seven DFREIs in the Type 34 message. If the SBAS provider needs to increase more than seven DFREIs by more than one DFREI value, then the SBAS provider has two options, either set satellites that cannot be coded in the DFREI field to “Do Not Use for SBAS”, or provide DFREIs using the Type 35 or Type 36 message. The SBAS provider can broadcast a DFRECI set to 0 corresponding to an existing higher DFREI value when a lower one could be broadcast. The DFRECI bump is not cumulative and can apply to any broadcast DFREI that could still be valid. Each Type 32 satellite correction message contains a DFREI. Any DFREI sent in a Type 32 message is valid until its time-out unless a new DFREI has been sent in multiple consecutive Types 34, 35 or 36 messages. When SBAS sends a new DFREI in all integrity messages broadcast during the DFREI validity period, SBAS can consider that the user will have the new DFREI and that the DFREI value broadcast in the previous Type 32 message has been replaced.

6.7.5.3 Use of DFMC SBAS integrity message for alerting. When an SBAS augments 53 or fewer satellites or uses the Type 34 message, the SBAS can send an alarm sequence using consecutive Type 34 or Type 35 messages and meet the alarm requirement. When an SBAS augments more than 53 satellites and chooses to use the Type 35/36 message pair, the alert logic becomes more complex. If all the satellites for which an alert needs to be sent are in the same message type, then that message type could be broadcast multiple times to meet the alert requirement. If the satellites that require an alert are contained across both the Type 35 and Type 36 messages, then it will be necessary to transition to use the Type 34 message or a Type 0 message to alert these

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

satellites. The use of the Type 34 message is the preferred option to limit service disruption since the use of Type 0 message requires recovery of all SBAS data.

6.7.6 *DFREI scale table update.* The Type 37 message contains integrity related parameters which are used in the DFMC SBAS HPL and VPL equations. In particular, the Type 37 message contains a DFREI scale table which provides the link between broadcast DFREI values and the associated dual-frequency range error sigma value to use in the protection level computation. Since the Type 37 message content is related to SBAS design, the expectation is that the Type 37 message parameters will change rarely. However, when the Type 37 message content does change, the SBAS provider will need to ensure that SBAS receivers maintain integrity during the change. The SBAS provider can achieve this through the broadcast of Type 0 message to clear SBAS receivers of the old Type 37 message data, through the inflation of broadcast DFREI values for all satellites, by alerting specific satellites that might not maintain integrity, or with no change if SBAS receivers will maintain integrity when using any valid broadcast Type 37 message data.

6.7.7 *Time-to-alert.* Figure D-2 also provides explanatory material in the frame of DFMC SBAS for the allocation of the total time-to-alert defined in Chapter 3, Table 3.7.2.4-1.

6.7.8 *Tropospheric function.* A tropospheric delay estimate for precision approach is described in 6.5.4.

6.7.9 *Multipath considerations.* Multipath is the largest contributors to positioning errors for DFMC SBAS affecting both ground and airborne elements in particular due to ionosphere-free combination of SBAS corrected dual-frequency measurements. Mitigation techniques for SBAS ground elements, described in 6.5.5, are also valid in DFMC SBAS.

6.7.10 *Week number rollover.* The week number rollover count ($WNRO_{count}$) value of 15 indicates that parameter is not valid. The DFMC SBAS receiver may use the $WNRO_{count}$ parameter to solve the possible ambiguity of the truncated week number value (WN_x) transmitted through the GNSS navigation data if the SBAS broadcast a $WNRO_{count}$ between 0 and 14. In this case, the $WNRO_{count}$ is processed as follows:

- If the current truncated week number (WN_x) of the GNSS constellation designated by a Type 37 message is equal to the maximum value $\overline{WN} - 1$, and the current day number of week is 7 and the reference time t_a corresponds to day number of week 1 in the GNSS constellation reference time, the total number of weeks (WN) elapsed since the beginning of the GNSS reference time is given by:

$$WN = (WNRO_{count} - 1) \times \overline{WN} + WN_x = WNRO_{count} \times \overline{WN} - 1$$

- If the current truncated week number (WN_x) of the GNSS constellation designated by a Type 37 message is 0, and the current day number of week is 1 and the reference time t_a corresponds to day number of week 7 in the GNSS constellation reference time, the total number of weeks (WN) elapsed since the beginning of the GNSS constellation reference time is given by:

$$WN = (WNRO_{count} + 1) \times \overline{WN} + WN_x = (WNRO_{count} + 1) \times \overline{WN}$$

- Otherwise:

$$WN = WNRO_{count} \times \overline{WN} + WN_x$$

6.7.11 *Day crossovers considerations.* The parameters t_d , t_a and t_e are expressed in seconds of day, adjusted for day crossovers. The following mechanism can be used at the user level to determine the reference day for a t_d ,

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 72

t_a or t_e parameter received in a message broadcast at epoch t . Taking the case of a t_a parameter, with t and t_d expressed in seconds of day:

- If $-43\ 200 \leq (t_d - t) \leq 43\ 199$, t_a is expressed in seconds of the message broadcast day;
- If $(t_d - t) < -43\ 200$, t_a is expressed in seconds of the next day of the message broadcast day; and
- If $(t_d - t) > 43\ 199$, t_a is expressed in seconds of the previous day of the message broadcast day;

The previous mechanism can be applied to t_a and t_e , replacing t_d by t_a or t_e .

6.7.12 *Position computation in DFMC SBAS*. Appendix B, 3.5.12.4 provides the protocol to compute SBAS position out of two augmented constellations by an SBAS. Assuming that an SBAS augments N number of constellations, N being equal to three or more, the linearized weighted least square estimate X includes $N - 2$ additional elements for the time offsets between the additional constellation and the reference constellation 1. In addition, the observation matrix G , described in Appendix B, 3.5.12.4 c), is modified to integrate $N - 2$ additional columns of time parameters. Those time parameters equal 1 for all satellites of this specific constellation when setting the parameter for the column number corresponding to the time offset column of this constellation in X . Those time parameters equal 0 otherwise.

6.7.12.1 *Alternative observation matrix G*. The DFMC SBAS navigation solution can be computed with the following observation matrix G as an alternative to the one defined in Appendix B, 3.5.12.4:

$$G_i = [-\cos E_{l_i} \cdot \sin A_{z_i} \quad -\cos E_{l_i} \cdot \cos A_{z_i} \quad -\sin E_{l_i} \quad n_{i,1} \quad n_{i,2}] = i^{\text{th}} \text{ row of } G$$

where

- $n_{i,1}$ is “1” if the satellite is part of reference constellation C1 or “0” if the satellite is part of constellation C2;
- $n_{i,2}$ is “0” if the satellite is part of reference constellation C1 or “1” if the satellite is part of constellation C2;

If the i^{th} row of G corresponds to a SBAS ranging measurement:

- $n_{i,1}$ is “1” if C1 is GPS or “0” otherwise;
- $n_{i,2}$ is “1” if C2 is GPS or “0” otherwise.

If the SBAS providing SBAS ranging measurement is not augmenting GPS, the SBAS clock offset needs to be solved by an additional unknown:

- $n_{i,3}$ is “1” if C1 and C2 are different than GPS (additional unknown to solve the clock offset of the SBAS satellite ranging constellation).

The navigation solution vector obtained with the alternative observation matrix is:

$$X = [x, y, z, ct_{c1}, ct_{c2}]$$

where

- ct_{c1} is the clock bias of the receiver with respect to constellation 1 reference time;
- ct_{c2} is the clock bias of the receiver with respect to constellation 2 reference time.

6.7.13 Dual PRNs from one SBAS satellite

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 73

6.7.13.1 *Assignment of SBAS PRN codes to satellites.* For vertically-guided approach operations, the system safety analysis expects user equipment to track two different satellites (as identified by PRN code), if available, to improve continuity of the operation. The broadcast of two PRNs from the same SBAS satellite introduces the SBAS satellite as a common failure between the two SBAS PRNs and might not provide the same level of continuity for these operations.

6.7.13.2 *Multiple SBAS range from the same satellite.* A concern with the broadcast of two ranging PRNs from the same SBAS satellite is that user equipment will use both ranging sources as if they were independent. If there are two ranging PRNs from the same SBAS satellite, the DFMC SBAS mask can prohibit use of both ranging signals in the same position solution for the DFMC SBAS user since the DFMC SBAS user is required to use all information from a single SBAS PRN. Therefore, an SBAS should preclude use of the second SBAS ranging signal from the same satellite by ensuring that the second ranging SBAS PRN satellite slot number is not set to “1” in the satellite mask received from the first SBAS PRN signal and vice-versa.

6.7.14 *Test operations.* Prior to certification for aviation use, SBAS broadcasts a Type 0 Do Not Use message. Aviation equipment will process this Type 0 message by clearing SBAS data received from that SBAS satellite. During pre-operational testing when the SBAS is able to compute valid data, some SBAS providers can broadcast valid data in the Type 0 message. Non-safety of life receivers might decide to use this data to calculate SBAS position solutions. For the L1 messages, some SBAS providers populated the Type 0 message with Type 2 data content. For the L5 message, SBAS providers may populate the Type 0 message with the content of Type 34, Type 35 or Type 36 messages. To identify which of these three integrity messages content is broadcast under Type 0 message, SBAS providers can use bits 222 and 223, with the following convention:

“00” No integrity data.

“01” Type 34 data content.

“10” Type 35 data content.

“11” Type 36 data content.

SBAS providers may choose a different coding of Type 0 messages in test operation.

6.7.15 *Non-geostationary satellite consideration.* There are several considerations for non-geostationary satellites. With higher satellite eccentricity, the deviations in power and Doppler shift require more consideration from the SBAS provider. Based on analysis, when the eccentricity exceeds 0.15, then the power differential from the orbit will exceed 3 dB and require some onboard power control function. The range change in the orbit will cause a constant power satellite bus to have broadcast power outside of either the maximum or minimum required power at some point during the orbit. When the eccentricity is above 0.3, the satellite Doppler shift at perigee will exceed the maximum specified Doppler shift. Some user equipment might no longer be able to track this satellite at perigee. Generally, highly eccentric orbits are used to increase satellite dwell time over a particular region during the apogee portion of the orbit. Therefore, the inability of user equipment to track the satellite around perigee might not impact the intended SBAS service. The Doppler shift for non-GEO SBAS is set to ± 7 kHz in Appendix B, 3.5.14.1.4, in line with these analyses.

6.7.16 *SNT-to-UTC conversion*

6.7.16.1 Users compute the time referenced in SNT at each epoch by solving the DFMC SBAS navigation solution. The optional Type 42 message provides the parameters to convert the time referenced in SNT into time referenced in UTC.

6.7.16.2 SNT is aligned on the core constellation time identified by the SBAS time reference identifier broadcast in the Type 37 message. The core constellation broadcasts parameters to convert the core constellation time into UTC, without an associated validity period. An SBAS service provider can broadcast a Type 42 message with

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 74

UTC conversion parameters corresponding to the ones broadcast by the reference core constellation, without guarantee on the validity period by setting the validity period parameter to “000”. SBAS service providers can broadcast a Type 42 message with other validity period values to provide a more accurate UTC conversion service (see Appendix B, 3.5.11.6).

6.7.16.3 Under nominal operation, the UTC conversion parameters broadcast in the Type 42 message are valid during a period of time equal to the validity period parameter. The UTC offset status parameter provides a mechanism to invalidate parameters broadcast in the previous Type 42 message and for which the validity period (VP) has not timed out. In that case, users should discard the UTC conversion parameters from the previous Type 42 message and start using the parameters contained in the latest received Type 42 message, if any provided (i.e. UTC standard identifier not set to 7).

7. Ground-Based Augmentation System (GBAS) and Ground Based Regional Augmentation System (GRAS)

Note - In this section, except where specifically annotated, reference to approach with vertical guidance (APV) means APV-I and APV-II.

7.1 System description

7.1.1 GBAS consists of ground and aircraft elements. A GBAS ground subsystem typically includes a single active VDB transmitter and broadcast antenna, referred to as a broadcast station, and multiple reference receivers. A GBAS ground subsystem may include multiple VDB transmitters and antennas that share a single common GBAS identification (GBAS ID) and frequency as well as broadcast identical data. The GBAS ground subsystem can support all the aircraft subsystems within its service volume providing the aircraft with approach data, corrections and integrity information for GNSS satellites in view. GBAS ground and aircraft elements are classified according to the types of service they support (as defined in section 7.1.2)

7.1.2 GBAS systems may provide two types of services: approach services and the GBAS positioning service. The approach service provides deviation guidance for within the approach service volume. The GBAS positioning service provides horizontal position information to support RNAV operations within the positioning service volume. The two types of services are also distinguished by different performance requirements associated with the particular operations supported (see Table 3.7.2.4-1) including different integrity requirements as discussed in 7.5.1.

7.1.2.1 GBAS approach services are further differentiated into multiple types referred to as GBAS approach service types (GAST). A GAST is defined as the matched set of airborne and ground performance and functional requirements that are intended to be used in concert in order to provide approach guidance with quantifiable performance. Four types of approach service, GAST A, GAST B, GAST C and GAST D are currently defined. GAST A, B and C are intended to support typical APV I, APV II and Category I operations, respectively. GAST D has been introduced to support landing and guided take-off operations in lower visibility conditions including Category III operations. Note that provisions for a separate service type to support Category II operations, but not Category I nor Category III, have not been made. Since equipment supporting GAST D will function the same when supporting Category II minima as when supporting Category III minima, GAST D provides one means of supporting Category II operations. Category II operations may potentially be supported using GAST C in conjunction with an appropriate aeroplane level integration. A relevant analogy is the authorization in at least one State of lower than Category I minima based on guidance from a facility performance Category I ILS used in conjunction with a head-up display (HUD). Requirements for the approval of Category II operations using GBAS will be defined by the airworthiness and operational approval authorities within BCAA.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 75

7.1.2.1.1 A GBAS ground subsystem may support multiple service types simultaneously. There are two types of ground subsystems, those that support multiple types of approach service and those that do not. Equipment designed in compliance with earlier versions of these SARPs may only support a single type of approach service, GAST C. Equipment designed in compliance with these SARPs may or may not support multiple types of service on one or more runway ends. The type of services supported for each approach are indicated in the approach performance designation field in a FAS data block within the Type 4 message. The GBAS continuity/integrity designator (GCID) parameter in the Type 2 message indicates whether a GBAS ground subsystem is currently supporting multiple types of approach service. Airborne equipment that can support multiple service types will first check the GCID to determine if the ground segment supports multiple types of service. If it does, the equipment will then check the approach performance designator (APD) field of the selected FAS data block within the Type 4 message to determine which types of service are supported by the ground segment for the approach selected (using the channel selection scheme described in section 7.7 below). The airborne equipment will then determine which approach service to select based on APD, the current status of GCID and the airborne equipment type. Operators should understand that the available operations may be restricted by many factors including pilot qualifications or temporary ANSP limitations which are not reflected in the APD value. Therefore, APD should not be interpreted as an indication of the availability of any operational use, only as an indication of the service types that are supported for the given runway.

7.1.2.1.2 GBAS airborne equipment may attempt to automatically select the highest type of service supported by both the airborne equipment and the ground segment for the selected approach (as indicated in APD). If the desired type of service is not available, the airborne equipment may select the next lower available type of service and announce this appropriately. Therefore, during a GBAS operation, there is the selected service type (SST) and the active service type (AST). The SST is the service type that the airborne equipment would use if it were available, and can be no higher than the highest type of service offered by the ground segment for the selected approach. The AST is the service type that the airborne equipment is actually using at a particular time. The AST may differ from the SST if the SST is unavailable for some reason. The airborne equipment announces both the SST and AST so that proper action (e.g. annunciations) may be taken in the context of the airborne integration and operational procedures.

7.1.2.1.3 Service providers should give consideration to what service type or types are actually required for each runway given the planned operations and encode the availability of the appropriate service types in the APD field of the associated FAS block.

7.1.2.1.4 When the ground subsystem is no longer capable of meeting FAST D requirements there are several options, depending upon which requirements are not met. If the ground subsystem cannot meet all of the FAST D integrity requirements (Appendix B, 3.6.7.1.2.1.1.2, 3.6.7.1.2.1.1.3, and 3.6.7.1.2.2.1.1, 3.6.7.3.2) FAST D needs to be removed within the time to alert defined in Appendix B, 3.6.7.1.2.1.1.3. If it is still capable of meeting FAST C integrity requirements, the ground subsystem should only remove FAST D and continue to broadcast in FAST C mode. The procedure for removing FAST D includes two options for reflecting this in the corrections (Appendix B, 3.6.7.3.2.1).

When downgrading from FAST D to C, the GCID in the Type 2 message (Appendix B, 3.6.7.2.3.2) also needs to change. A FAST D ground subsystem normally broadcasts a GCID of 2, indicating it supports FAST C and FAST D. When the ground subsystem can no longer support FAST D, but can still support FAST C, the GCID should change to 1. Note that it is assumed here that a FAST D ground subsystem would downgrade to FAST C only, and not to FAST A or B.

Another condition that could result in the ground subsystem no longer being capable of supporting FAST D would be a failure such that FAST D continuity (Appendix B, 3.6.7.1.3.1 and 3.6.7.1.3.2) cannot be met (e.g. failure of redundant components). If FAST D integrity requirements are still met, the ground subsystem is not required to remove the corrections in the Type 11 messages. However, the GCID needs to change to 1. Communicating the

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 76

change in GCID nominally would take 10 seconds, as the minimum update rate for Type 2 messages is 10 seconds. It may take as long as one minute. A change in FAST should be reflected in the next scheduled broadcast of the Type 2 message. In addition, changes to GCID are ignored by the airborne equipment when the aircraft is in the final stages of the approach. Therefore, GCID changes only affect the FAST for aircraft outside of the final stages of the approach.

7.1.3 A significant distinguishing feature for GBAS ground subsystem configurations is whether additional ephemeris error position bound parameters are broadcast. This feature is required for the positioning service, but is optional for some approach services. If the additional ephemeris error position bound parameters are not broadcast, the ground subsystem is responsible for assuring the integrity of ranging source ephemeris data without reliance on the aircraft calculating and applying the ephemeris bound as discussed in 7.5.9.

7.1.4 GBAS configurations. There are multiple configurations possible of GBAS ground subsystems conforming to the GNSS Standards, examples of such configurations are:

- a) a configuration that supports GAST C only;
- b) a configuration that supports GAST A, GAST B, GAST C, and also broadcasts the additional ephemeris error position bound parameters;
- c) a configuration that supports GAST C and GAST D, and the GBAS positioning service, while also broadcasting the ephemeris error position bound parameters referred to in b); and
- d) a configuration that supports only GAST A and the GBAS positioning service, and is used within a GRAS.

7.1.4.1 *GBAS facility classification (GFC)*. A GBAS ground subsystem is classified according to key configuration options. A GFC is composed of the following elements:

- a) facility approach service type (FAST);
- b) ranging source types;
- c) facility coverage; and
- d) polarization

7.1.4.1.1 *Facility approach service type (FAST)*. The FAST is a collection of letters from A to D indicating the service types that are supported by the ground subsystem. For example, FAST C denotes a ground subsystem that meets all the performance and functional requirements necessary to support GAST C. As another example, a FAST ACD designates a ground subsystem that meets the performance and functional requirements necessary to support service types A, C and D.

Note.— The facility classification scheme for GBAS includes an indication of which Service Types the ground subsystem can support. This means the ground subsystem meets all the performance requirements and functional requirements such that a compatible airborne user can apply the information from the ground subsystem and have quantifiable performance at the output of the processing. It does not necessarily mean that the ground subsystem supports all service types on every runway end. Which GBAS approach service types are supported on a given runway end is indicated in the Type 4 message and is included as part of the approach facility designation defined in section 7.1.4.2.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 77

7.1.4.1.2 *Ranging source types*: The ranging source type designation indicates what ranging sources are augmented by the ground subsystem. The coding for this parameter is as follows:

- G1 - GPS
- G2 - SBAS
- G3 - GLONASS
- G4 - Reserved for Galileo
- G5+ - Reserved for future ranging sources

7.1.4.1.3 Facility coverage: The facility coverage designation indicates positioning service capability and maximum use distance. The facility coverage is coded as 0 for ground facilities that do not provide the positioning service. For other cases, the facility coverage indicates the radius of D_{max} expressed in nautical miles.

Note.— The service volume for specific approaches is defined as part of the approach facility designations defined in section 7.1.4.2.

7.1.4.1.4 Polarization: The polarization designation indicates the polarization of the VHF data broadcast (VDB) signal. E indicates elliptical polarization and H indicates horizontal polarization.

7.1.4.1.5 GBAS facility classification examples. The facility classification for a specific facility is specified by a concatenated series of codes for the elements described in sections 7.1.4.1 through 7.1.4.1.4. The general form of the facility classification is:

GFC = Facility Approach Service Type/Ranging Source Type /Facility Coverage/Polarization.

For example, a facility with the designation of GFC – C/G1/50/H, denotes a ground subsystem that meets all the performance and functional requirements necessary to support service type C on at least one approach, using GPS ranges only, with the GBAS positioning service available to a radius of 50 NM from the GBAS reference position and a VDB that broadcasts in Horizontal polarization only. Similarly, GFC - CD/G1G2G3G4/0/E denotes a ground subsystem that supports at least one approach with a service type of C and D, provides corrections for GPS, SBAS, GLONASS and Galileo satellites, does not support the positioning service and broadcasts on elliptical polarization.

7.1.4.2 Approach facility designations. A GBAS ground subsystem may support many approaches to different runway ends at the same airport or even runways at adjacent airports. It is even possible that a GBAS will support multiple approaches to the same runway end with different Types of Service (intended, for example, to support different operational minima). Each approach provided by the ground system may have unique characteristics and in some sense may appear to the user to be a separate facility. Therefore, in addition to the GBAS facility classification, a system for classifying or designating the unique characteristics of each individual approach path is needed. For this purpose a system of approach facility designations is defined. Figure D-XX illustrates the relationship between GBAS facility classifications and approach facility designations. The classification is intended to be used for pre-flight planning and published in the AIP.

7.1.4.2.1 Approach facility designation elements. Each approach supported by a GBAS can be characterized by an approach facility designation (AFD). The AFD is composed of the following elements:

GBAS identification: Indicates the GBAS facility identifier that supports the approach (4-character GBAS ID).

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 78

Approach identifier: This is the approach identifier associated with the approach in the Message Type 4 data block. It is 4 characters and must be unique for each approach within radio range of the GBAS facility.

Channel number: This is the channel number associated with the approach selection. It is a 5 digit channel number between 20001 and 39999.

Approach service volume: Associated with each published approach, indicates the service volume either by a numerical value in feet corresponding to the minimum decision height (DH) or by the GBAS points as defined below (i.e. GBAS Points A, B, C, T, D, E, or S).

Supported service types: Designates the GBAS service types (A-D) that are supported for the approach by the ground subsystem. This field can never be given a value greater than the facility approach service type for the GBAS ground subsystem that supports the approach.

The GBAS points A, B, C, T, D and E define the same locations relative to the runway as the ILS Points in Attachment C, Figure C-1 used to define the ILS localizer course and glide path bend amplitude limits. Point S is a new point defining the stop end of the runway. For GBAS, the points are used to indicate the location along the nominal approach and/or along the runway for which GBAS performance for the supported service type(s) has been verified. When a decision height is used instead to define the approach service volume, the service volume is provided to a height of half the DH as defined in Chapter 3, 3.7.3.5.3.1. The choice of coding using a DH or GBAS points depends upon the intended operational use of the runway. For example, if the approach identifier corresponds to a Category I instrument approach procedure from which automatic landings are authorized, the approach service volume element is intended to indicate at what point along the runway the performance has been verified. The point definitions are given below:

GBAS Point “A”. A point on a GBAS final approach segment measured along the extended runway centre line in the approach direction a distance of 7.5 km (4 NM) from the threshold.

GBAS Point “B”. A point on the GBAS final approach segment measured along the extended runway centre line in the approach direction a distance of 1 050 m (3 500 ft) from the threshold.

GBAS Point “C”. A point through which the downward extended straight portion of the nominal GBAS final approach segment passes at a height of 30 m (100 ft) above the horizontal plane containing the threshold.

GBAS Point “D”. A point 3.7 m (12 ft) above the runway centre line and 900 m (3 000 ft) from the threshold in the direction of the GNSS azimuth reference point (GARP).

GBAS Point “E”. A point 3.7 m (12 ft) above the runway centre line and 600 m (2 000 ft) from the stop end of the runway in the direction of the threshold.

GBAS Point “S”. A point 3.7 m (12 ft) above the runway centre line at the stop end of the runway.

GBAS reference datum (Point “T”). A point at a height specified by TCH located above the intersection of the runway centre line and the threshold.

7.1.4.2.2 Approach facility designation examples

The approach facility designation consists of the concatenation of the parameters defined in section 7.1.4.2.1 as: GBAS ID/approach ID/ranging sources/approach service volume/required service type. An example application of this concept to a particular approach at the US Washington, DC Ronald Reagan International Airport is:

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 79

“ DCA/XDCA/21279/150/CD”

where:

KDCA – indicates the approach is supported by the GBAS installation at DCA

XDCA – indicates the approach ident (echoed to the pilot on approach selection) for this specific approach is “XDCA”

21279 – is the 5-digit channel number used to select the approach

150 – indicates the GBAS coverage has been verified to be sufficient to support a DH as low as 150 ft.

CD – indicates that GBAS approach service types C and D are supported by the ground subsystem for the approach

Another example application of this concept to a particular approach at Boeing Field is:

“ BFI/GBFI/35789/S/C”

where:

KBFI – indicates the approach is supported by the GBAS installation at BFI (with GBAS Station identifier KBFI)

GBFI – indicates the approach ident (echoed to the pilot on approach selection) for this specific approach is “GBFI”

35789 – is the 5-digit channel number used to select the approach.

S – indicates the GBAS service volume extends along the approach and the length of the runway surface (i.e. 12 ft above the runway to the stop end).

C – indicates that GBAS approach service type C is supported by the ground subsystem for this FAS.

7.1.4.3 GBAS airborne equipment classification (GAEC)

GBAS airborne equipment may or may not support multiple types of approach service that could be offered by a specific ground subsystem. The GBAS airborne equipment classifications (GAEC) specifies which subsets of potentially available services types the airborne equipment can support. The GAEC includes the following elements:

Airborne approach service type (AAST): The AAST designation is a series of letters in the range from A to D indicating which GASTs are supported by the airborne equipment. For example, AAST C denotes airborne equipment that supports only GAST C. Similarly, AAST ABCD indicates the airborne equipment can support GASTs A, B, C & D.

Note.— For airborne equipment, designating only the highest GBAS approach service type supported is insufficient as not all airborne equipment is required to support all service types. For example, a particular type of airborne equipment may be classified as AAST CD, meaning the airborne equipment supports GAST C and D (but not A or B).

Ranging source types: This field indicates which ranging sources can be used by the airborne equipment. The coding is the same as for the ground facility classification (see section 7.1.4.1.2).

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 80

7.1.4.3.1 *Multiple service type capable equipment.* Ground and airborne equipment designed and developed in accordance with previous versions of these SARPs (Amendment 80) and RTCA DO-253A will only support GAST C. The current version of the Standards has been designed such that legacy GBAS airborne equipment will still operate correctly when a ground subsystem supports multiple types of service. Also, airborne equipment which can support multiple types of service will operate correctly when operating with a ground subsystem that supports only GAST C.

7.1.4.3.2 *GBAS airborne equipment classification examples.* GBAS airborne equipment classifications consist of a concatenated series of codes for the parameters defined in 7.1.4.3. The general form of the GAEC is:

GAEC = (airborne approach service type)/(ranging source type)

For example:

GAEC of C/G1 - denotes airborne equipment that supports only GAST C and uses only GPS ranges.

Similarly:

GAEC of ABC/G1G4 - denotes airborne equipment that supports all GASTs except GAST D and can use both GPS and Galileo ranging sources.

GAEC of ABC/G1G3 - denotes airborne equipment that supports all GASTs except GAST D and can use both GPS and GLONASS ranging sources.

Finally:

GAEC – CD/G1G2G3G4 - denotes airborne equipment that supports GASTs C and D and uses GPS, SBAS, GLONASS and Galileo ranging sources.

7.1.5 *GRAS configurations.* From a user perspective, a GRAS ground subsystem consists of one or more GBAS ground subsystems (as described in 7.1.1 through 7.1.4), each with a unique GBAS identification, providing the positioning service and one or more approach service types where required. By using multiple GBAS broadcast stations, and by broadcasting the Type 101 message, GRAS is able to support en-route operations via the GBAS positioning service, while also supporting terminal, departure, and operations supported by GAST A or B over a larger coverage region than that typically supported by GBAS. In some GRAS applications, the corrections broadcast in the Type 101 message may be computed using data

obtained from a network of reference receivers distributed in the coverage region. Type 101 message may be computed using data obtained from a network of reference receivers distributed in the coverage region. This permits detection and mitigation of measurement errors and receiver faults.

7.1.6 *VDB transmission path diversity.* All broadcast stations of a GBAS ground subsystem broadcast identical data

with the same GBAS identification on a common frequency. The airborne receiver need not and cannot distinguish between messages received from different broadcast stations of the same GBAS ground subsystem. When within coverage of two such broadcast stations, the receiver will receive and process duplicate copies of messages in different time division multiple access (TDMA) time slots.

7.1.7 Interoperability of the GBAS ground and aircraft elements compatible with RTCA/DO-253() is addressed in Appendix B, 3.6.8.1. GBAS receivers compliant with RTCA/DO-253A will not be compatible with GRAS ground subsystems broadcasting Type 101 messages. However, GRAS and GBAS receivers compliant with RTCA/DO-310 GRAS MOPS, will be compatible with GBAS ground subsystems. SARPs-compliant GBAS receivers may not be able to decode the FAS data correctly for GAST A transmitted from GBAS ground

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 81

subsystems (i.e. a FAS data block with APD coded as “0”). These receivers will apply the FASLAL and FASVAL as if the active service type is GAST C. ANSPs should be cognizant of this fact and relevant operational restrictions may have to be applied to ensure the safety of the operation. For GBAS ground subsystems providing GAST D, APD in the FAS data blocks may be coded as values of 1 or 2 (Appendix B, 3.6.4.5.1). SARPs compliant GBAS receivers developed in accordance with SARPs prior to Amendment 91 may not be able to use FAS data blocks with APD equal to 2 or above.

7.1.8 The GBAS VDB transmits with either horizontal or elliptical polarization (GBAS/H or GBAS/E). This allows service providers to tailor the broadcast to their operational requirements and user community.

7.1.9 The majority of aircraft will be equipped with a horizontally-polarized VDB receiving antenna, which can be used to receive the VDB from both GBAS/H and GBAS/E equipment. A subset of aircraft will be equipped with a vertically-polarized antenna due to installation limitations or economic considerations. These aircraft are not compatible with GBAS/H equipment and are, therefore, limited to GBAS-based operations supported by GBAS/E.

7.1.10 GBAS service providers must publish the signal polarization (GBAS/H or GBAS/E), for each GBAS facility in the aeronautical information publication (AIP). Aircraft operators that use vertically polarized receiving antenna will have to take this information into account when managing flight operations, including flight planning and contingency procedures.

7.1.11 *Availability considerations for GBAS.* A single GBAS ground subsystem may provide multiple types of service to multiple users and service for multiple runway ends simultaneously. These different types of service may have different availability and consequently one type of service may be available when another is not. Furthermore, as some elements of GBAS are optional (e.g. augmentation of multiple constellations or use of SBAS ranging sources), the capabilities of different users will vary. For this reason, it is not practical for the service provider to predict if a given user will find a specific service type to be available at any given time. All that can be known by the service provider is the status of the ground subsystem and satellite constellation. An assessment can be made as to whether the ground subsystem is meeting the allocated requirements for some target service type and further, the availability of service can be predicted based on an assumed level of performance and a nominal user. The definition of the nominal user includes which elements of GNSS are used (core satellite systems, SBAS ranges etc.) and within that, which subset of satellites are used in the position solution. For GBAS supporting GAST D this is further complicated by the fact that certain parameters (e.g. geometry screening thresholds) may be adjusted by the airframe designer to ensure adequate landing performance given the characteristics of the specific aircraft type. ANSPs and air space designers should be cognizant of the fact that availability of service for GNSS augmentation systems in general is less predictable than conventional navigation aids. Variations in user capabilities will result in times where service may be available to some users and unavailable to others.

7.2 RF characteristics

7.2.1 Frequency coordination

7.2.1.1 Performance factors

7.2.1.1.1 The geographical separation between a candidate GBAS station, a candidate VOR station and existing VOR or GBAS installations must consider the following factors:

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

- a) the service volume, minimum field strength and effective isotropically radiated power (EIRP) of the candidate GBAS including the GBAS positioning service, if provided. The minimum requirements for service volume and field strength are found in Chapter 3, 3.7.3.5.3 and 3.7.3.5.4.4, respectively. The ERP is determined from these requirements;
- b) the coverage and service volume, minimum field strength and EIRP of the surrounding VOR and GBAS stations including the GBAS positioning service, if provided. Specifications for coverage and field strength for VOR are found in Chapter 3, 3.3, and respective guidance material is provided in Attachment C;
- c) the performance of VDB receivers, including co-channel and adjacent channel rejection, and immunity to desensitization and intermodulation products from FM broadcast signals. These requirements are found in Appendix B, 3.6.8.2.2;
- d) the performance of VOR receivers, including co-channel and adjacent channel rejection of VDB signals. Since existing VOR receivers were not specifically designed to reject VDB transmissions, desired-to-undesired (D/U) signal ratios for co-channel and adjacent channel rejection of the VDB were determined empirically. Table D-2 summarizes the assumed signal ratios based upon empirical performance of numerous VOR receivers designed for 50 kHz channel spacing;
- e) for areas/regions of frequency congestion, a precise determination of separation may be required using the appropriate criteria;

Table D-5. Assumed $[D/U]_{\text{required}}$ signal ratios to protect VOR from GBAS VDB

Frequency offset	$[D/U]_{\text{required}}$ ratio to protect VOR receivers (dB)
Co-channel	26
$ f_{\text{VOR}} - f_{\text{VDB}} = 25 \text{ kHz}$	0
$ f_{\text{VOR}} - f_{\text{VDB}} = 50 \text{ kHz}$	-34
$ f_{\text{VOR}} - f_{\text{VDB}} = 75 \text{ kHz}$	-46
$ f_{\text{VOR}} - f_{\text{VDB}} = 100 \text{ kHz}$	-65

- f) that between GBAS installations RPDS and RSDS numbers are assigned only once on a given frequency within radio range of a particular GBAS ground subsystem. The requirement is found in Appendix B, 3.6.4.3.1;
- g) that between GBAS installations within radio range of a particular GBAS ground subsystem the reference path identifier is assigned to be unique. The requirement is found in Appendix B, 3.6.4.5.1; and
- h) the four-character GBAS ID to differentiate between GBAS ground subsystems. The GBAS ID is normally identical to the location indicator at the nearest aerodrome. The requirement is found in Appendix B, 3.6.3.4.1. and

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 83

- i) Slot assignment. The relative assignment of slots to a GBAS ground subsystem can impact performance in instances where messages in multiple slots need to be received by the airborne subsystem prior to processing. This will occur when using linked messages and/or for a GAST D ground subsystem where correction data is contained in both the Type 1 and Type 11 messages. In these cases slot assignments for all MT 1 and 11 should be adjacent to avoid unnecessary latency and complexity of design. Non-adjacent assignments may, depending on the design of the ground subsystem, result in a lack of time for the ground subsystem to process fault detections, render some slot combinations unusable and thus result in lower efficiency of spectrum use.

7.2.1.1.2 Nominal link budgets for VDB are shown in Table D-3. The first example in Table D-3 assumes a user receiver height of 3 000 m (10 000 ft) MSL and a transmit antenna designed to suppress ground illumination in order to limit the fading losses to a maximum of 10 dB at VDB coverage edge. In the case of GBAS/E equipment, the 10 dB also includes any effects of signal loss due to interference between the horizontal and vertical components. The second example in Table D-3 provides a link budget for longer range positioning service. It is for a user receiver height sufficient to maintain radio line-of-sight with a multi-path limiting transmitting antenna. No margin is given in table D-3 for fading as it is assumed that the receiver is at low elevation angles of radiation and generally free from significant null for the distances shown in the table (greater than 50 NM). In practice, installations will experience a fade margin that will be dependent on many parameters including aircraft altitude, distance from transmit antenna, antenna type/design and ground reflectors.

7.2.1.2 FM immunity

7.2.1.2.1 Once a candidate frequency is identified for which the GBAS and VOR separation criteria are satisfied, compatibility with FM transmissions must be determined. This is to be accomplished using the methodology applied when determining FM compatibility with VOR. If FM broadcast violates this criterion, an alternative candidate frequency has to be considered.

7.2.1.2.2 The desensitization is not applied for FM carriers above 107.7 MHz and VDB channels at 108.050 MHz because the off-channel component of such high-level emissions from FM stations above 107.7 MHz will interfere with GBAS VDB operations on 108.025 and 108.050 MHz, hence those assignments will be precluded except for special assignments in geographic areas where the number of FM broadcast stations in operation is small and would unlikely generate interference in the VDB receiver.

7.2.1.2.3 The FM intermodulation immunity requirements are not applied to a VDB channel operating below 108.1 MHz, hence assignments below 108.1 MHz will be precluded except for special assignments in geographic areas where the number of FM broadcast stations in operation is small and would unlikely generate intermodulation products in the VDB receiver.

7.2.1.3 Geographic separation methodologies

7.2.1.3.1 The methodologies below may be used to determine the required GBAS-to-GBAS and GBAS-to-VOR geographical separation. They rely on preserving the minimum desired -to -undesired signal ratio. $[D/U]_{\text{required}}$ is defined as the signal ratio intended to protect the desired signal from co-channel or adjacent channel interference from an undesired transmission. $[D/U]_{\text{required}}$ values required for protection of a GBAS receiver from undesired GBAS or VOR signals are defined in Appendix B, 3.6.8.2.2.5 and 3.6.8.2.2.6. $[D/U]_{\text{required}}$ values intended for protection of a VOR receiver from GBAS VDB transmissions as shown in Table D-2 are not defined in SARPs and represent the assumed values based on test results.

7.2.1.3.2 Geographic separation is constrained by preserving $[D/U]_{\text{required}}$ at the edge of the desired signal coverage where the desired signal power is derived from the minimum field strength requirements in Chapter 3.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

This desired signal level, converted to dBm, is denoted $P_{D,min}$. The allowed signal power of the undesired signal ($P_{U,allowed}$) is:

$$P_{U,allowed}(dBm) = (P_{D,min} (dBm) - [D/U]_{required} (dB))$$

The undesired signal power P_U converted to dBm is:

$$P_U(dBm) = (Tx_U (dBm) - L (dB))$$

where

Tx_U is the effective radiated power of the undesired transmitter; and

L is the transmission loss of the undesired transmitter, including free-space path loss, atmospheric and ground effects. This loss depends upon the distance between the undesired transmitter and the edge of the desired signal coverage.

To ensure $D/U_{required}$ is satisfied, $P_u \leq D_{U,allowed}$. The constraint for assigning a channel is therefore:

$$L(dB) \geq ([D/U]_{required} (dB) + Tx_U(dBm) - P_{D,min} (dBm))$$

7.2.1.3.3 The transmission loss can be obtained from standard propagation models published in ITU-R Recommendation P.528-2 or from free-space attenuation until the radio horizon and then a constant 0.5 dB/NM attenuation factor. These two methodologies result in slightly different geographical separation for co-channel and first adjacent channels, and identical separation as soon as the second adjacent channel is considered. The free-space propagation approximation is applied in this guidance material.

7.2.1.4 Example of GBAS/GBAS geographical separation criteria

7.2.1.4.1 For GBAS VDB co-channel transmissions assigned to the same time slot, the parameters for horizontal polarization are

$$\begin{aligned} D/U &= 26 \text{ dB (Appendix B, 3.6.8.2.2.5.1);} \\ PD_{,mi} &= -72 \text{ dBm (equivalent to 215 microvolts per meter, Chapter 3,} \\ n &= 3.7.3.5.4.4); \text{ and} \\ Tx_U &= 47 \text{ dBm (example link budget, Table D-3);} \end{aligned}$$

so

$$L \geq (47 + 26 - (-72)) = 145 \text{ dB.}$$

7.2.1.4.2 The geographic separation for co-channel, co-slot GBAS VDB assignments is obtained by determining the distance at which the transmission loss equals 145 dB for receiver altitude of 3 000 m (10 000 ft) above that of the GBAS VDB transmitter antenna. This distance is 318 km (172 NM) using the free-space attenuation approximation and assuming a negligible transmitter antenna height. The minimum required geographical separation can then be determined by adding this distance to the nominal distance between the edge of VDB coverage and the GBAS transmitter 43 km (23 NM). This results in a co-channel, co-slot reuse distance of 361 km (195 NM).

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 85

7.2.1.5 Guidelines on GBAS/GBAS geographical separation criteria. Using the methodology described above, typical geographic separation criteria can be defined for GBAS to GBAS and GBAS to VOR. The resulting GBAS/GBAS minimum required geographical separation criteria are summarized in Table D-4.

Note.— Geographical separation criteria between the GBAS transmitters providing the GBAS positioning service are under development. A conservative value corresponding to the radio horizon may be used as an interim value for separation between co-frequency, adjacent time slot transmitters to ensure time slots do not overlap.

7.2.1.6 Guidelines on GBAS/VOR geographical separation criteria. The GBAS/VOR minimum geographical separation criteria are summarized in Table D-5 based upon the same methodology and the nominal VOR coverage volumes in Attachment C.

Table D-6. Nominal VDB link budget

<i>VDB link elements</i>

390 (200)	125	51.9	155	55.9	389	

Notes—

- It is possible, with an appropriately sited multipath limiting VDB transmitting antenna with an effective radiated power sufficient to meet the field strength requirements for approach service and considering local topographical limitations, to also satisfy the field strength requirements such that positioning service can be supported at the ranges in this table.*
- Actual aircraft implementation loss (including antenna gain, mismatch loss, cable loss, etc.) and actual receiver sensitivity may be balanced to achieve the expected link budget. For example, if the aircraft implementation loss for the horizontal component is 19 dB, the receiver sensitivity must exceed the minimum requirement and achieve -91 dBm to satisfy the nominal link budget.*
- The long-range performance estimates may generally be optimistic with the assumption of no fade margin, i.e., link budget performance will generally not be as good as these estimates indicate.*

Note 1.— When determining the geographical separation between VOR and GBAS, VOR as the desired signal is generally the constraining case due to the greater protected altitude of the VOR coverage region.

Note 2.— Reduced geographical separation requirements can be obtained using standard propagation models defined in ITU-R Recommendation P.528-2.

7.2.2 The geographical separation criteria for GBAS/ILS and GBAS/VHF communications are under development.

7.2.3 Compatibility with ILS. Considerations for assignment of VDB channels include the frequency separation between the ILS and the VDB, the distance separation between the ILS coverage area and the VDB, the VDB and ILS field strengths, and the VDB and ILS localizer receiver sensitivity. Until

compatibility criteria are developed for GBAS VDB and ILS, VDB can generally not be assigned to channels below 112.025 MHz (i.e. a minimum frequency separation of 75 kHz from the highest assignable ILS localizer frequency).

7.2.3.1 Inter-airport compatibility. The minimum geographical separation based on a minimum frequency separation of 75 kHz between ILS localizer and GBAS ground station deployed at different airports is 3 NM between the undesired transmitter antenna location and the edges of the coverage of the desired service that are assumed to be at minimum signal power. Smaller necessary separation distance values may be obtained by taking into account additional information such as the actual desired service field strength and actual undesired service transmit antenna radiation patterns.

Note.— The coverage of the ILS localizer is standardized in Chapter 3, section 3.1.3.3 and the GBAS service volume is standardized in Chapter 3, section 3.7.3.5.3, respectively.

7.2.3.2 Same-airport compatibility. To analyse the constraints for the deployment of a GBAS ground station at the same airport as ILS, it is necessary to consider ILS and VDB compatibility in detail taking into account information such as the actual desired service field strength and actual undesired service transmit antenna radiation patterns. For GBAS equipment with transmitter power such that the maximum field strength of 0.879 volts per metre (-27 dBW/m²) for the horizontally polarized signal component is not exceeded in the ILS coverage volume, the 16th channel (and beyond) will be below -100.5 dBm in a 25 kHz bandwidth at a distance of 80 m from the VDB transmitter, including allowance for a +5 dB increase due to constructive multipath. This -100.5106 dBm in a 25 kHz bandwidth translates to a signal-to-noise ratio of 21.5 dB (above the assumed minimum signal-to-noise ratio of 20 dB) for a -79 dBm localizer signal which corresponds to an ILS localizer field strength of 90 microvolts per metre (minus 107 dBW/m²)

Note.— When deploying GBAS and ILS at the same airport, it is recommended to also analyse the impact of the GBAS VDB transmission on the ILS localizer monitor. Interference may be avoided by installing an appropriate filter.

7.2.4 Compatibility with VHF communications. For GBAS VDB assignments above 116.400 MHz, it is necessary to consider VHF communications and GBAS VDB compatibility. Considerations for assignment of these VDB channels include the frequency separation between the VHF communication and the VDB, the distance separation between the transmitters and coverage areas, the field strengths, the polarization of the VDB signal, and the VDB and VHF communication receiver sensitivity. Both aircraft and ground VHF communication equipment are to be considered. For GBAS/E equipment with a transmitter maximum power of up to 150 W (100 W for horizontal component and 50 W for vertical component), the 64th channel (and beyond) will be below -112 dBm in a 25 kHz bandwidth at a distance of 80 m from the VDB transmitter including an allowance for a +5 dB increase due to constructive multipath. For GBAS/H equipment with a transmitter maximum power of 100 W, the 32nd channel (and beyond) will be below -120 dBm at a distance of 200 m from the VDB transmitter including allowing for a +5 dB positive reflection, and a 10 dB polarization isolation. It must be noted that due to differences in the VDB and VDL transmitter masks, separate analysis must be performed to ensure VDL does not interfere with the GBAS VDB

Table D-7. Typical GBAS/GBAS frequency assignment criteria

Channel of undesired VDB in the same time slots	Path loss (dB)	Minimum required geographical separation for T _{XU} = 47 dBm and P _{D,min} = -72 dBm in km (NM)
Cochannel	145	361 (195)
1st adjacent channel (±25 kHz)	101	67 (36)

2nd adjacent channel (± 50 kHz)	76	44(24)
3rd adjacent channel (± 75 kHz)	73	No restriction
4th adjacent channel (± 100 kHz)	73	No restriction

Note 1.— No geographic transmitter restrictions are expected between co-frequency, adjacent time slots provided the undesired VDB transmitting antenna is located at least 200 m from areas where the desired signal is at minimum field strength.

Note 2.— The PD,min of -72 dBm is the output from an ideal isotropic antenna.

Table D-8. Minimum required geographical separation for a VOR coverage (12 000 m (40 000 ft) level)

Channel of undesired GBAS VDB	Path loss (dB)	VOR coverage radius		
		342 km (185 NM)	300 km (162 NM)	167 km (90 NM)
Co-channel	152	892 km (481 NM)	850 km (458 NM)	717 km (386 NM)
$ f_{\text{Desired}} - f_{\text{Undesired}} = 25$ kHz	126	774 km (418 NM)	732 km (395 NM)	599 km (323 NM)
$ f_{\text{Desired}} - f_{\text{Undesired}} = 50$ kHz	92	351 km (189 NM)	309 km (166 NM)	176 km (94 NM)
$ f_{\text{Desired}} - f_{\text{Undesired}} = 75$ kHz	80	344 km (186 NM)	302 km (163 NM)	169 km (91 NM)
$ f_{\text{Desired}} - f_{\text{Undesired}} = 100$ kHz	61	No restriction	No restriction	No restriction

Note - Calculations are based on reference frequency of 112 MHz and assume GBAS $T_{XU} = 47$ dBm and VOR $P_{D,min} = -79$ dBm.

7.2.5 For a GBAS ground subsystem that only transmits a horizontally-polarized signal, the requirement to achieve the power associated with the minimum sensitivity is directly satisfied through the field strength requirement. For a GBAS ground subsystem that transmits an elliptically-polarized component, the ideal phase offset between HPOL and VPOL components is 90 degrees. In order to ensure that an appropriate received power is maintained throughout the GBAS service volume during normal aircraft manoeuvres, transmitting equipment should be designed to radiate HPOL and VPOL signal components with an RF phase offset of 90 degrees. This phase offset should be consistent over time and environmental conditions. Deviations from the nominal 90 degrees must be accounted for in the system design and link budget, so that any fading due to polarization loss does not jeopardize the minimum receiver sensitivity. System qualification and flight inspection procedures will take into account an allowable variation in phase offset consistent with maintaining the appropriate signal level throughout the GBAS service volume. One method of ensuring both horizontal and vertical field strength is to use a single VDB antenna that transmits an elliptically-polarized signal, and flight inspect the effective field strength of the vertical and horizontal signals in the service volume.

7.3 Service volume

7.3.1 The minimum GBAS service volume to support approach services is depicted in Figure D-5. Where practical, it is operationally advantageous to provide valid guidance along the visual segment of an approach. The lateral approach service volume may be different (larger) than the vertical approach service volume. When the additional ephemeris error position bound parameters are broadcast, differential corrections may only be used within the Maximum Use Distance (Dmax) defined in the Type 2 message. It is also allowable for Dmax to extend beyond an approach service volume. Reasons why this may be desirable include providing pilots with situational awareness and GBAS status information prior to intercepting the approach procedure, and

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 89

improving GBAS course capture at the limits of the service volume. In such cases, the potential for reduced protection level, ephemeris bound, and VDB continuity outside the approach service volume should be considered especially when broadcasting large or unlimited values of Dmax.

7.3.1.1 If a GBAS installation supports multiple approach service volumes, use of a single omnidirectional data broadcast covering all intended service volumes should be considered to limit complexity, if geographically feasible.

7.3.1.2 In addition, autoland or guided take-off may be used at facilities or runways not intended to support or not currently supporting Category II or III operations using GBAS. Even in Category I or better visual conditions, use of an approved autoland system with GAST C can aid pilots in achieving stabilized approaches and reliable touchdown performance, for Category II or III training, to exercise the airborne system to ensure suitable performance, and for maintenance checks. Use of this capability may also provide pilot workload relief. Similarly, use of an approved guided take-off system will also provide operational benefits. Autoland and guided take-off service volume requirements are contained in Chapter 3, 3.7.3.5.3.2. VDB reception on the runway surface is significantly affected by the transmit antenna design and its installed height as well as the geography of the airport. Service along all runways at an airport using a single VDB antenna/transmitter location may be difficult. However, where practical, service to support autoland and guided take-off operations should be provided at suitable runways supporting any precision approach. The approach service volume element of the approach facility designation allows this information to be contained in the AIP (refer to 7.1.4.2.1). A useful autoland capability may be achievable for some aircraft even when the requirements of Chapter 3, 3.7.3.5.3.2 are not entirely met. Similarly, some aircraft may not be able to conduct automatic landings with only the minimum service volume provided. For approaches with a FAS data path not aligned with the runway centre line, autoland service volume is not required.

7.3.2 An increased signal power (-62.5 dBm) from 36 ft and above, compared to the minimum requirement set for the GBAS service volume at 12 ft above the ground (-72 dBm), is required above the runway surface to accommodate various implementations of airborne VDB antenna. Indeed, VDB antenna height and aircraft implementation loss might not be suitable to meet adequate continuity for autoland under Category III conditions and guided take-off if:

- a) aircraft VDB antenna height located above 12 ft may induce more than the expected 15 dB aircraft implementation loss; and
- b) aircraft VDB antenna height located below 12 ft may receive a signal power that is below the minimum required value of -72 dBm.

To mitigate a lack of adequate VDB link budget, actual aircraft implementation loss (including type of antenna and location of antenna on the fuselage, antenna gain, mismatch loss, cable loss, etc.) and actual receiver sensitivity may be balanced to achieve the expected link budget. The need for additional operational mitigations might be identified and implemented during the aircraft approval process in case of potential loss of VDB along the flight path. It is common practice that a verification flight test is performed by a candidate operator to perform autoland under Category III conditions on a given runway.

It is not practical to measure the signal strength at 36 ft. Therefore, two example means of verification are identified below:

- Simplified analysis method: Measure the signal at 12 ft and estimate the signal strength at 36 ft using mathematical tools;

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 90

Complex analysis method: Model the airport configuration and simulate, using a mathematical tool, the signal strength at 12 ft and 36 ft.

Note 1.— There exists an upper limit in the autoland service volume above the runway surface set at 100 ft.

Note 2.— Verification of minimum signal strength at 36 ft is sufficient to ensure compliance above 36 ft.

7.3.2.1 Simplified analysis method.

In order to apply this method, it is assumed the following:

- VDB transmitters are installed above a planar ground with line-of-sight to runways in the desired GBAS service volume as mentioned in Attachment D, 7.12.3.

The analysis methodology consists of:

- Ground subsystem manufacturers and/or service providers perform a generic (non-airport specific) analysis to show that signal strength requirements at both 12 ft and 36 ft can be met based on distance from and height of the VDB antenna at their specific location. Studies have shown that signal strength will increase from the signal strength measured at 12 ft in various airport configurations. When verifying compliance for a specific installation, an acceptable means of compliance is to measure the signal strength at 12 ft and estimate the signal strength by using the following formula:

To estimate the power (in dBm) at a height h (in metres) from the power at a height h_0 (in metres), one can use the following expression.

$$P_{hdBm} = P_{h_0dBm} + 20 \log \left(\sin \left(\frac{2\pi h h_a}{\lambda d} \right) \right) - 20 \log \left(\sin \left(\frac{2\pi h_0 h_a}{\lambda d} \right) \right)$$

where

- d is the distance to the transmitter antenna in metres
- h_a is the height of the transmitter antenna phase centre in metres
- $\lambda = c / f$ is the wavelength in metres
- f is the frequency in Hertz
- c is the speed of light

For $h < \frac{\lambda d}{8h_a}$, the previous formulation can be approximated with an error smaller than 1dB as follows:

$$P_{hdBm} = P_{h_0dBm} + 20 \log \left(\frac{h}{h_0} \right)$$

Alternatively, converting heights in feet and considering, $h_0^{ft} = 12$ ft, the previous expressions become:

$$P_{hdBm} = P_{h_0dBm} + 20 \log \left(\sin \left(\frac{0.584 h^{ft} h_a^{ft}}{\lambda d} \right) \right) - 20 \log \left(\sin \left(\frac{7 h_a^{ft}}{\lambda d} \right) \right)$$

and

$$P_{hdBm} = P_{h_0dBm} + 20 \log(h^{ft}) - 21.58dB$$

The applicability of the above-mentioned formula at different heights above the runway surface may vary with the distance between the VDB transmitter and the intended path on the runway surface and the VDB transmitter antenna height. Some siting constraints may be needed to verify the minimum signal strength is met in the service volume above the runway surface.

7.3.2.2 Complex analysis method.

This method assumes that:

Airport configuration is so complex that “noise like multipath” (multipath reflections from buildings or aircraft standing or moving) cannot be easily accounted for and must be addressed in the analysis;

and/or

Line-of-sight between the VDB antenna and runway cannot be maintained.

The analysis methodology consists of:

The airport configuration includes relevant surfaces such as buildings and metallic fences, and topology of the ground surface is modeled with their electromagnetic characteristics. Radiation pattern of the VDB transmitter antenna is also modeled.

Signal powers at 12 ft and 36 ft are estimated by simulating radio propagation. One of the acceptable means of the simulation is the ray-tracing method based on geometric optics. Such simulation is available with commercially available software with an intuitive human-machine interface to the airport modeling.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 92

□ Effects of small-scale (less than 5-10 wavelengths) structures limit the accuracy of simulation by the ray-tracing method. Therefore, an additional margin to represent such effects may need to be added to the simulation results.

□ The signal power at 12 ft is measured and compared with the simulated one. If the measured and simulated signal powers at 12 ft match well, the simulation can be regarded as being able to model the signal powers at different heights over the runway.

□ The simulated signal power and the minimum requirement at 36 ft are compared to verify the compliance of the VDB coverage over the runway.

7.3.3 The service volume required to support the GBAS positioning service is dependent upon the specific operations intended. The optimal service volume for this service is intended to be omnidirectional in order to support operations using the GBAS positioning service that are performed outside of the approach service volume. ANSP is responsible for defining a service volume for the GBAS positioning service and ensuring that the requirements of Chapter 3, 3.7.2.4 are satisfied. When making this determination, the characteristics of the fault-free GNSS receiver should be considered, including the reversion to ABAS-based integrity in the event of loss of GBAS positioning service.

7.3.4 The limit on the use of the GBAS positioning service information is given by the Maximum Use Distance (D_{max}). D_{max} however does not delineate the coverage area where field strength requirements specified in Chapter 3, 3.7.3.5.4.4 are necessarily met nor matches this area. Accordingly, operations based on the GBAS positioning service can be predicated only in the service volume(s) (where performance requirements are met) within the D_{max} range.

7.3.5 As the desired coverage area of a GBAS positioning service may be greater than that which can be provided by a single GBAS broadcast station, a network of GBAS broadcast stations can be used to provide the coverage. These stations can broadcast on a single frequency and use different time slots (8 available) in neighboring stations to avoid interference or they can broadcast on different frequencies. Figure D-4A details how the use of different time slots will allow a single frequency to be used without interference subject to guard time considerations noted under Table B-59. For a network based on different VHF frequencies, guidance material in 7.17 should be considered.

7.4 Data structure

A bit scrambler/descrambler is shown in Figure D-5.

Note - Additional information on the data structure of the VHF data broadcast is given in RTCA/DO-246B, GNSS Based Precision Approach Local Area Augmentation System (LAAS) —Signal-in-Space Interface Control Document (ICD).

7.5 Integrity

7.5.1 Different levels of integrity are specified for precision approach operations and operations based on the GBAS positioning service. The signal-in-space integrity risk for approach services is 2×10^{-7} per approach. GBAS ground subsystems that are also intended to support other operations through the use of the GBAS positioning service have to also meet the signalin-space integrity risk requirement specified for terminal area operations, which is 1×10^{-7} /hour (Chapter 3, Table 3.7.2.4-1). Therefore additional measures are necessary to support these more stringent requirements for positioning service. The signalin-space integrity risk is allocated between the ground subsystem integrity risk and the

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

protection level integrity risk. The ground subsystem integrity risk allocation covers failures in the ground subsystem as well as core constellation and SBAS failures such as signal quality failures and ephemeris failures. For GAST A, B, and C the protection level integrity risk allocation covers rare fault-free position domain performance risks and the case of failures in one of the reference receiver measurements. In both cases the protection level equations ensure that the effects of the satellite geometry used by an aircraft fault-free receiver are taken into account. This is described in more detail in the following paragraphs. For GAST D, the position domain integrity is delegated to the aircraft and a FAST D ground subsystem provides additional data and ranging source monitoring for aircraft using this service type.

7.5.1.1 Additional integrity requirements apply for GAST D, which is intended to support precision approach and automatic landing in low visibility conditions with minima less than Category I. The same requirements for bounding the position solution within a protection level that is compared to an alert limit apply, for all error sources except single ground reference receiver faults and errors induced by ionospheric anomalies. Single ground reference receiver faults are mitigated as described in 7.5.11. The responsibility for some errors induced by anomalous ionospheric conditions has been allocated to the airborne equipment. Mitigation of errors due to ionospheric anomalies is described in 7.5.6.1.6. Additional monitoring requirements and design assurance requirements are needed to allow a FAST D GBAS ground subsystem to provide a service that can provide equivalent safety to Category III ILS operations. Some additional monitoring requirements are allocated to the ground subsystem (see 7.5.6.1 to 7.5.6.1.7) and some are allocated to the airborne equipment. The additional monitoring performance requirements for the ground subsystem can be found in Appendix B, 3.6.7.3.3.

7.5.1.2 The ground subsystem integrity risk requirement for GAST D (Appendix B, section 3.6.7.1.2.1.1.3) limits the probability of a ground subsystem failure resulting in the transmission of erroneous data during a minimum exposure time of “any one landing.” Typically the critical period of exposure to failures for vertical guidance in Category III operations is taken to be the period between the Category I Decision Height (200 ft) and the threshold (50 ft height). This is nominally 15 seconds, depending upon the aircraft approach speed. The critical period of exposure to failures for lateral guidance in Category III operations is taken to be the period between the Category I Decision Height and completion of the roll-out, which occurs when the aircraft decelerates to a safe taxi speed (typically less than 30 knots). This is nominally 30 seconds, again depending upon the aircraft approach speed and rate of deceleration. The term “any one landing” is used to emphasize that the time period where faults could occur extends prior to the critical period of exposure. The reason for this is that the fault may develop slowly over time; it could occur earlier in the landing phase and become a hazard during the critical period of exposure.

7.5.1.3 The critical period of exposure to failure for lateral guidance during a guided take-off in low visibility conditions is nominally 60 seconds. Erroneous or loss of guidance during a guided take-off being less critical than for Category III landings, it does not introduce any changes to the ground subsystem integrity requirements.

7.5.2 The GBAS ground subsystem defines a corrected pseudo-range error uncertainty for the error relative to the GBAS reference point (σ_{pr_gnd}) and the errors resulting from vertical (σ_{tropo}) and horizontal (σ_{iono}) spatial decorrelation. These uncertainties are modelled by the variances of zero-mean, normal distributions which describe these errors for each ranging source.

7.5.3 The individual error uncertainties described above are used by the receiver to compute an error model of the navigation solution. This is done by projecting the pseudo-range error models to the position domain. General methods for determining that the model variance is adequate to guarantee the protection level integrity risk are described in Section 14. The lateral protection level (LPL) provides a bound on the lateral position error with a probability derived from the integrity requirement. Similarly, the vertical protection level (VPL) provides a bound on the vertical position. For Category I precision approach and APV, if the computed LPL exceeds the lateral alert limit (LAL) or the VPL exceeds the vertical alert limit (VAL), integrity is not adequate to support the operation. For the positioning service the alert limits are not defined in the standards, with only the horizontal protection level and ephemeris error position bounds required to be computed and applied. The alert limits will be determined based on the operation being conducted. The aircraft will apply the computed protection level and ephemeris bounds by verifying they are smaller than the alert limits. Two protection levels are defined, one to address the condition when all reference receivers are fault-free (H_0 – Normal Measurement Conditions), and one to address the condition when one of the reference receivers contains failed measurements (H_1 – Faulted Measurement Conditions). Additionally an ephemeris error position bound provides a bound on the position error due to failures in ranging source ephemeris. For Category I precision approach and APV, a lateral error bound (LEB) and a vertical error bound (VEB) are defined. For the positioning service a horizontal ephemeris error bound (HEB) is defined.

7.5.3.1 The GBAS signal-in-space integrity risk (Appendix B, 3.6.7.1.2.1.1) is defined as the probability that the ground subsystem provides information which when processed by a fault-free receiver, using any combination of GBAS data allowed by the protocols for data application (Appendix B, 3.6.5), results in an out-of-tolerance lateral or vertical relative position error without announcement for a period longer than the maximum time-to-alert. An out-of-tolerance lateral or vertical relative position error is defined as an error that exceeds the GBAS approach services protection level and, if additional data block 1 is broadcast, the ephemeris error position bound. Hence it is the responsibility of the ground subsystem to provide a consistent set of data including the differential corrections, and all parameters that are used by the protocols for data application (e.g, σ_{pr_gnd} and the B values as defined in the Type 1 message), so that the protection levels bound the position error with the required integrity risk. This error bounding process must be valid for any set of satellites that the user might be using. To ensure the computed protection levels actually bound the error with the required probability, it may in some cases be necessary to inflate or otherwise manipulate one or more of the parameters that are used by the protocols for data application. For example, to address the impact of anomalous ionospheric effects one strategy that has been used is to inflate σ_{pr_gnd} and $\sigma_{vert_iono_gradient}$ to ensure that airborne equipment that complies with the protocols for data application will be adequately protected.

7.5.4 Ground system contribution to corrected pseudo-range error (σ_{pr_gnd}). Error sources that contribute to this error include receiver noise, multipath, and errors in the calibration of the antenna phase centre. Receiver noise has a zero-mean, normally distributed error, while the multipath and antenna phase centre calibration can result in a small mean error.

7.5.5 Residual tropospheric errors. Tropospheric parameters are broadcast in Type 2 messages to model the effects of the troposphere, when the aircraft is at a different height than the GBAS reference point. This error can be well-characterized by a zero-mean, normal distribution.

7.5.6 Residual ionospheric errors. An ionospheric parameter is broadcast in Type 2 messages to model the effects of the ionosphere between the GBAS reference point and the aircraft. This error can be well-characterized by a zero-mean, normal distribution.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 95

7.5.6.1 Ionospheric anomalies. Small scale structures in the ionosphere can result in non-differentially corrected errors in the GBAS position. Such phenomena are typically associated with solar storm activity and may be characterized by steep gradients in the ionospheric delay over a relatively short distance (e.g. a few tens of kilometres). The errors that may be induced by these phenomena result when the airborne receiver and ground subsystem are receiving satellite signals that have different propagation delays. Also, since GBAS uses code-carrier smoothing with a relatively long time constant, biases build up in these filters that are a function of the rate of change of ionospheric delay. If the ground subsystem and airborne receivers experience significantly different delays and rates of change of the ionospheric delays, the biases that build up in these filters will not match and will not be cancelled by the differential processing.

7.5.6.1.1 Ionospheric anomaly mitigation. Ionospheric anomalies can produce position errors which are significant (i.e. tens of metres) in the context of approach operations. To mitigate these errors, different strategies are used depending on the GBAS approach service type.

7.5.6.1.2 Ionospheric anomaly mitigation for GAST A, B and C. For GAST A, B or C, the ground subsystem is responsible for mitigating the potential impact of ionospheric anomalies. This may be handled through various monitoring schemes (e.g. far-field monitors or integration with a wide area ground network supporting SBAS) which detect the presence of ionosphere anomalies and deny service if the resulting user position errors would be unacceptable. One means to deny service is to inflate some combination of the broadcast integrity parameters: σ_{pr_gnd} , $\sigma_{vert_iono_gradient}$, the ephemeris decorrelation parameter (P), the ephemeris missed detection parameters $K_{md_e,GPS}$ and $K_{md_e,GLONASS}$ such that any geometry that could be used by an airborne user will not be subjected to intolerably large errors (given the intended operational use). This inflation scheme could also be used without the complexity of monitoring the ionosphere during operations by assuming ionosphere anomalies are present. In this case, a model of the possible ionosphere conditions that could occur is used to determine the proper values of the broadcast integrity parameters. Since the extremes of ionosphere conditions vary significantly through the world, the model is location dependent. Such an inflation scheme results in a reduction in availability because it inflates the values even when anomalies are not present.

7.5.6.1.3 Ionospheric anomaly mitigation for GAST D. Requirements for monitoring and geometry screening in the airborne equipment have been introduced for GAST D to mitigate the potential impact of ionospheric anomalies. The airborne monitoring consists of monitoring the code-carrier divergence continuously in order to detect large gradients in the ionosphere. In addition, the airborne equipment will screen geometries to ensure that an unacceptably large amplification of residual pseudo-range errors (i.e. errors that may exist after airborne monitoring has been applied) will not occur. Another factor which is useful for the mitigation of errors induced by ionospheric anomalies is the use of the 30-second carrier smoothed pseudo-ranges in a position solution. (The shorter time constant smoothing is inherently less susceptible to filter bias mismatch errors.) Finally, GAST D includes parameters: $K_{md_e_D,GLONASS}$, $K_{md_e_D,GPS}$, PD and $\sigma_{vert_iono_gradient_D}$, which are intended to be used in place of the parameters $K_{md_e,GLONASS}$, $K_{md_e,GPS}$, P, and $\sigma_{vert_iono_gradient}$, respectively, when the active service type is GAST D. This is done so that if the ground subsystem employs inflation of the parameters $K_{md_e_D,GLONASS}$, $K_{md_e_D,GPS}$, P and $\sigma_{vert_iono_gradient_D}$ to mitigate the effects of ionospheric anomalies for GAST A, B or C, the GAST D user can be provided with non-inflated parameters for use in GAST D where airborne monitoring is employed to address the ionospheric anomaly errors. This enables GAST D service to have improved availability.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

7.5.6.1.4 Bounding of ionospheric anomaly errors. As stated above, ionospheric anomalies may be addressed by inflating one or more of the parameters: σ_{pr_gnd} , $\sigma_{vert_iono_gradient}$, the ephemeris decorrelation parameter (P), the ephemeris missed detection parameters $K_{md_e,GPS}$ and $K_{md_e,GLONASS}$. The ground subsystem is responsible for providing values in these parameters such that the error is appropriately bounded by the VPL and HPL computations at the output of a fault free receiver. In GAST D, responsibility for mitigation of errors due to anomalous ionospheric conditions has been divided between the airborne subsystem and the ground subsystem. Although GAST D still requires the protection levels to bound the errors (as described in 7.5.3.1), they are not required to bound the errors that result from an anomalous ionospheric event as is the case for GAST C. Hence, the protection levels as computed with PD, $K_{md_e_D,GLONASS}$, $K_{md_e_D,GPS}$, and $\sigma_{vert_iono_gradient_D}$ must bound the error for all error sources as discussed in 3.6.7.1.2.1.1.2 except for the errors due to anomalous ionospheric conditions. The protection level computations must bound the nominal ionospheric errors.

7.5.6.1.5 Dual solution ionospheric gradient monitoring. Another component of the airborne mitigation of errors induced by ionospheric anomalies is by the use of dual position solutions computed simultaneously with two different carrier smoothing time constants (see 7.19.3). This dual solution computation has two purposes. Firstly, taking the difference of two corrected pseudo-range measurements as detection statistics allows the filter build-up errors on each satellite, due to large differences in ionospheric gradients between the ground measurements and airborne measurements, to be directly observable. Hence a threshold can be applied to these detection statistics in order to detect a large portion of the ionospheric anomalies. The second application of the dual solutions is to compute a bound for the 30-second smoothed position (excluding the impact of ionospheric anomalies). The data provided by the ground segment allows a protection level bound to be computed for the 100-second solution. By adding the direct observation of the magnitude of the difference between the 30-second smoothed position and the 100-second smoothed position, to the protection level computation, a protection level is obtained, which is guaranteed to bound the 30-second position solution with the required 1×10^{-7} /approach. This allows airborne equipment, with an active service type of D to provide equivalent bounding performance, as required for approaches to Category I minima even though the 30-second solution is used to develop the guidance.

7.5.6.1.6 Requirements for FAST D ground subsystems to support mitigation of errors caused by ionospheric anomalies. Although much of the responsibility for mitigation of ionospheric errors is allocated to the airborne segment, there is a requirement for FAST D ground subsystems that is necessary to support mitigation of such effects. Appendix B, 3.6.7.3.4 specifies that the ground subsystem is responsible for ensuring mitigation of ionospheric spatial delay gradients. The ground subsystem ensures that the value of the maximum corrected pseudo-range error (EIG) computed from the Type 2 data does not exceed 2.75 metres at all LTPs associated with runways that support GAST D procedures. One option available to the manufacturer is to restrict the distance between the GBAS reference point and the LTP. It may, in some cases, be desirable to allow GAST D service at LTPs where EIG exceeds 2.75 m. This could have an impact on the availability of the GAST D service for that particular approach. The service provider should then evaluate whether the expected performance is adequate for the intended service. See 7.5.13.1 for guidance on how availability assessment can be done.

7.5.6.1.7 Ionospheric anomaly threat models used for GAST D validation. As discussed above, the mitigation of errors that could be induced by ionospheric anomalies is accomplished through a combination of airborne and ground system monitoring. The effectiveness of the required monitoring

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 97

has been demonstrated through simulation and analysis and the maximum errors at the output of the monitoring have been shown to be consistent with airworthiness certification criteria for a range of anomalies described below. This range of anomalies is described in terms of a “standard threat space” consisting of an ionospheric anomaly model which defines physical attributes of the ionospheric anomaly. The model described in 7.5.6.1.7.1 is a conservative rendition of the model developed for the continental United States. This model has been shown to bound the ionospheric threat evaluated in several other mid-latitude regions, relative to the magnetic equator. Recent data collected in some low-latitude regions, relative to the magnetic equator, has shown ionospheric conditions associated with local ionospheric density depletion (“plasma bubbles”) that exceed this threat model. Research has resulted, for example, in a reference low-latitude threat model for the Asia-Pacific Region by a dedicated Ionospheric Studies Task Force (APAC ISTF). The threat models define an ionospheric environment for which the standardized monitoring is known to produce acceptable performance on a per-pseudo-range basis. Each service provider should evaluate whether the standard threat space model described below is appropriate for the ionospheric characteristics in the region where GBAS is intended to support GAST D service. This evaluation should always be performed, regardless of the latitudes involved. If a service provider determines that the ionospheric behaviour is not adequately characterized by this threat model (e.g. for a region of uniquely severe ionospheric behaviour), that service provider must take appropriate action to ensure the users will not be subjected to ionospheric anomalies with characteristics outside the range of the standard threat space. The service provider may elect to:

1. alter the characteristics of its ground subsystem; and/or
2. introduce additional monitoring (internal or external to the GBAS); and/or
3. introduce other operational mitigations that limit users’ exposure to the extreme ionospheric conditions.

Potential ground subsystem changes which could achieve this risk reduction include tighter siting constraints (see 7.5.6.1.6) and improved ground subsystem monitoring performance (Appendix B, 3.6.7.3.4). Another mitigation strategy is monitoring of space weather (external to the GBAS system) in conjunction with operational limitations on the use of the system during predicted periods of severely anomalous ionospheric activity. Combinations of these strategies may be used to ensure that the GAST D user is not subjected to ionospheric anomalies outside the standard threat space.

7.5.6.1.7.1 Ionosphere anomaly model: moving wedge. This models a severe ionospheric spatial gradient as a moving wedge of constant, linear change in slant ionosphere delay, as shown in Figure D-7. The key parameters of this model are the gradient slope (g) in mm/km, the width (w) of the wedge in km, the amplitude of the change in delay (D) in m, and the speed (v) at which the wedge moves relative to a fixed point on the ground. These values are assumed to remain (approximately) constant over the period in which this wedge affects the satellites tracked by a single aircraft completing a GAST D approach. While the width of the wedge is small, the “length” of the wedge in the East-North coordinate frame (i.e. how far the “ionospheric front” containing the wedge extends) is not constrained.

In this model, the upper bound on g is dependent on wedge speed as specified in Table D-5A. This value is not dependent on satellite elevation angle. Because g is expressed in terms of slant delay, no “obliquity” correction from zenith delay is needed. The width w can vary from 25 to 200 km. The maximum value of D is 50 m. Note that, to make the model consistent, D must equal the product of slope g and width w . In cases where slope and width each fall within their allowed ranges, but their product D exceeds the 50-metre bound, that combination of slope and width is not a valid point within

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

the threat model. For example, both $g = 400$ mm/km and $w = 200$ km are individually allowed, but their product equals 80 metres. Since this violates the constraint on D , a wedge with $g = 400$ mm/km and $w = 200$ km is not included in this threat model.

Note.— In the GAST D validation, it was assumed that each simulated wedge model is applied to the two ranging sources that produced the worst-case position errors. However, the numbers of wedges and impacted ranging sources depend on the ionospheric characteristics in the region where GBAS is intended to support GAST D service.

Table D-9. Upper bound on gradient slope

<i>Propagation speed (v)</i>	<i>Upper bound on gradient slope (g)</i>
$v < 750$ m/s	500 mm/km
$750 \leq v < 1500$ m/s	100 mm/km

7.5.6.1.8 Ionosphere gradient mitigation validation

7.5.6.1.8.1 Because the mitigation responsibility for spatial ionosphere gradients is shared between the airborne and ground subsystems, this section includes guidance for modeling the critical airborne components (e.g. aircraft motion and monitoring) which will enable a ground manufacturer to validate the mitigation of spatial ionosphere gradients from a total system perspective. The validation can take into account the combination of ground and airborne monitors for the detection of gradients. When accounting for the combination of monitors, the correlation or independence between the monitors needs to be considered. Monitor performance should also consider the effective time between independent samples of each monitor’s test statistic. Modeling of the ionosphere monitoring should include re admittance criteria for an excluded satellite, as appropriate per the ground subsystem design and DO-253D.

7.5.6.1.8.2 This section also includes test scenario guidance to help ensure all possible airborne position, ground reference point, approach direction, and gradient direction orientations are considered during validation.

7.5.6.1.8.3 Airborne monitor implementation

Validation may account for the following airborne monitors:

- a) airborne code carrier divergence filtering as described in 2.3.6.11 of DO-253D;
- b) differential RAIM used for satellite addition as described in 2.3.9.6.1 of DO-253D; and
- c) dual solution pseudo-range ionospheric gradient monitoring as described in 2.3.9.7 of DO-253D.

7.5.6.1.8.3.1 In assessing the probability of missed detection, the contribution of all noise sources to the test statistic used for the airborne code carrier divergence monitor, excluding the effects of the ionosphere, can be assumed to have a normal distribution with a zero mean and a standard deviation of 0.002412 m/s.

7.5.6.1.8.3.2 In assessing the probability of missed detection, the contribution of all noise sources to the test statistic used for the dual solution pseudo-range ionospheric gradient monitor can be assumed to have a normal distribution with a zero mean and a standard deviation of 0.1741 m.

7.5.6.1.8.3.3 Note that the prior probability of the gradient that can be utilized during validation of 3.6.7.3.4 applies for these airborne monitors as well.

7.5.6.1.8.4 Modeling airborne positioning and speed the airborne speed and position can be modeled working backward from the threshold crossing time using the following four values: a) speed at landing; b) amount of time at landing speed; c) deceleration rate; and d) speed at start of deceleration.

7.5.6.1.8.4.1 Figure D-8 illustrates how these four values are used to define a speed profile and Table D-5B shows the values that define the family of curves to be used in determination of GAST D broadcast parameters for a specific IGM design.

Table D-10. Airborne speed profile from initial position to LTP

<i>Landing ground speed (knots)</i>	<i>Time at landing speed (seconds)</i>	<i>Deceleration rate (knots/s)</i>	<i>Ground speed at start of deceleration (knots)</i>
161	50	1.1	290
148	50	1.1	277
135	50	1.1	264

Note. — Modeling aircraft altitude is not necessary.

7.5.6.1.8.4.2 Figure D-9 shows the approach speed profiles based on the values in Table D-5B in terms of ground speed versus time until the aircraft reaches the landing threshold point.

7.5.6.1.8.5 Gradient, airborne position, ground reference point, and approach direction considerations

7.5.6.1.8.5.1 Figure D-10 illustrates the basic anomalous ionospheric scenarios (A-D) that constitute a threat. For a given ground station installation, the ground manufacturer should demonstrate valid mitigation for any ionosphere gradient/airborne/approach orientations corresponding to that particular installation.

7.5.6.1.8.5.2 Validation test scenarios should also address the timing component for each orientation. For example, for a given scenario, an approach should be executed at least at one-minute intervals.

7.5.7 Aircraft receiver contribution to corrected pseudo-range error. The receiver contribution is bounded as described in Section 14. The maximum contribution, used for analysis by the GBAS provider, can be taken from the accuracy requirement, where it is assumed that σ_{receiver} equals $\text{RMS}_{\text{pr_air}}$ for GBAS Airborne Accuracy Designator A equipment.

7.5.8 Airframe multipath error. The error contribution from airframe multipath is defined in Appendix B, 3.6.5.5.1. Multipath errors resulting from reflections from other objects are not included. If experience indicates that these

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 100

errors are not negligible, they must be accounted for operationally or through inflation of the parameters broadcast by the ground (e.g. σ_{pr_gnd}).

7.5.9 Ephemeris error uncertainty. Pseudo-range errors resulting from ephemeris errors (defined as a discrepancy between the true satellite position and the satellite position determined from the broadcast data) are spatially decorrelated and will therefore be different for receivers in different locations. When users are relatively close to the GBAS reference point, the residual differential error due to ephemeris errors will be small and both the corrections and uncertainty parameters σ_{pr_gnd} sent by the ground subsystem will be valid to correct the raw measurements and compute the protection levels. For users further away from the GBAS reference point, protection against ephemeris failures can be ensured in two different ways:

- a) the ground subsystem does not transmit the additional ephemeris error position bound parameters. In this case, the ground subsystem is responsible for assuring integrity in case of satellite ephemeris failures without reliance on the aircraft calculating and applying the ephemeris bound. This may impose a restriction on the distance between the GBAS reference point and the decision altitude/height depending upon the ground subsystem means of detecting ranging source ephemeris failures. One means of detection is to use satellite integrity information broadcast by SBAS; and
- b) the ground subsystem transmits the additional ephemeris error position bound parameters which enable the airborne receiver to compute an ephemeris error bound. These parameters are: coefficients used in the ephemeris error position bound equations ($K_{md_e_()}$, where the subscript () means either “GPS”, “GLONASS”, “POS, GPS” or “POS, GLONASS”), the maximum use distance for the differential corrections (D_{max}), and the ephemeris decorrelation parameters (P). The ephemeris decorrelation parameter (P) in the Type 1 or Type 101 message characterizes the residual error as a function of distance between the GBAS reference point and the aircraft. The value of P is expressed in m/m. The values of P are determined by the ground subsystem for each satellite. One of the main factors influencing the values of P is the ground subsystem monitor design. The quality of the ground monitor will be characterized by the smallest ephemeris error (or minimum detectable error (MDE)) that it can detect. The relationship between the P parameter and the MDE for a particular satellite can be approximated by $P_i = MDE_i/R_i$ where R_i is the smallest of the predicted ranges from the ground subsystem reference receiver antenna(s) for the period of validity of P_i . Being dependent on satellite geometry, the P parameters values are slowly varying. However, it is not a requirement for the ground subsystem to dynamically vary P. Static P parameters could be sent if they properly ensure integrity. In this latter case, the availability would be slightly degraded. Generally, as MDE becomes smaller, overall GBAS availability improves.

7.5.10 Ephemeris error/failure monitoring. There are several types of monitoring approaches for detecting ephemeris errors/failures. They include:

- a) Long baseline. This requires the ground subsystem to use receivers separated by large distances to detect ephemeris errors that are not observable by a single receiver. Longer baselines translate to better performance in MDE;
- b) SBAS. Since SBAS augmentation provides monitoring of satellite performance, including ephemeris data, integrity information broadcast by SBAS can be used as an indication of ephemeris validity. SBAS uses ground subsystem receivers installed over very long baselines, therefore this provides optimum performance for ephemeris monitoring and thus achieves small MDEs; and
- c) Ephemeris data monitoring. This approach involves comparing the broadcast ephemeris over consecutive satellite orbits. There is an assumption that the only threat of failure is due to a failure in

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

ephemeris upload from the constellation ground control network. Failures due to uncommanded satellite manoeuvres must be sufficiently improbable to ensure that this approach provides the required integrity.

7.5.10.1 The monitor design (for example, its achieved MDE) is to be based upon the integrity risk requirements and the failure model the monitor is intended to protect against. A bound on the GPS ephemeris failure rate can be determined from the reliability requirements defined in Chapter 3, 3.1.7.3.1.4, since such an ephemeris error would constitute a major service failure.

7.5.10.2 The GLONASS control segment monitors the ephemeris and time parameters, and in case of any abnormal situation it starts to input the new and correct navigation message. The ephemeris and time parameter failures do not exceed 70 m of range errors. The failure rate of GLONASS satellite including the ephemeris and time parameter failures does not exceed 4×10^{-5} per satellite per hour.

7.5.11 A typical GBAS ground subsystem processes measurements from 2 to 4 reference receivers installed in the immediate vicinity of the reference point. The aircraft receiver is protected against a large error or fault condition in a single reference receiver by computing and applying the B parameters from the Type 1 or Type 101 message to compare data from the various reference receivers. Alternative system architectures with sufficiently high redundancy in reference receiver measurements may employ processing algorithms capable of identifying a large error or fault in one of the receivers. This may apply for a GRAS network with receivers distributed over a wide area and with sufficient density of ionospheric pierce points to separate receiver errors from ionospheric effects. The integrity can then be achieved using only the protection levels for normal measurement conditions (VPL_{H0} and LPL_{H0}), with appropriate values for K_{ffmd} and σ_{pr_gnd} . This can be achieved using the Type 101 message with the B parameters excluded.

7.5.11.1 GAST D ground reference receiver faults. For GAST D, there is an additional standardized monitor implemented in the airborne receiver used to maintain the single reference receiver faulted measurement condition integrity regardless of the satellite geometry used in the aircraft. The aircraft receiver computes a position error estimate based on the B parameters and compares that error estimate directly to a threshold set as low as possible consistent with acceptable continuity risk. Although the monitor is mechanized in the airborne subsystem, the ground subsystem must meet specific requirements for the monitor to provide the required protection. The integrity performance depends on the assumed a priori failure rate (Appendix B, 3.6.7.1.2.2.1.2) and the probability of missed detection of the monitor. The a priori rate of a single reference receiver providing faulted measurements is required to be less than 1×10^{-5} per 150 seconds. The rate per individual receiver is dependent upon the number of reference receivers in the ground subsystem. For example, with four reference receivers the rate per receiver would be required to be less than 2.5×10^{-6} per 150 seconds. This a priori rate is achieved through a combination of receiver design requirements and proper reference receiver siting and operational constraints. Because conditions during system operation vary, ground subsystems may monitor receiver outputs to verify continued compliance with the requirement. The integrity performance also depends on the probability of missed detection (Pmd) performance of the monitor implemented in the airborne equipment. The Pmd performance of this monitor in turn depends on the characteristics of the errors that confound the observability of a reference failure. This is also true for the existing protection level integrity risk equations associated with faulted measurement conditions. The ground subsystem is required to broadcast integrity parameters that bound the errors such that a normal distribution can sufficiently characterize the errors and the Pmd can be estimated (Appendix B, 3.6.7.1.2.2.1.1 and 3.6.7.2.2.4.1).

7.5.11.2 GAST D ground reference receiver fault magnitude bounding. Because the airborne subsystem implements the monitor as defined in the MOPS, it is possible to compute the size of the largest error

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 102

that can result from the failure of a single reference receiver with a probability of greater than 1×10^{-9} . The calculated maximum size of the error will depend on the assumed a priori failure rate (Appendix B, 3.6.7.1.2.2.1.1) and the probability of missed detection of the monitor. The monitor Pmd is dependent on the monitor threshold which is computed by the airborne equipment as a function of the geometry and the error distribution associated with the H1 hypothesis.

7.5.12 Range domain monitoring requirements for GAST D. To support equivalent safety of Category II/III operations, requirements beyond the basic “signal-in-space” requirements defined for GAST A, B and C are necessary. These requirements include performance requirements for monitors implemented to detect pseudo-range errors. Two requirements apply to the post monitoring error in the corrected pseudo-range due to specific ranging source failures (Appendix B, 3.6.7.3.3.2 and 3.6.7.3.3.3). In both cases, the requirement applies to the probability of missed detection as a function of the size of an error due to the failure in the 30-second smoothed pseudo-range after the correction is applied.

- 1) The first requirement constrains the Pmd performance of the specified ranging source failures without regard for the a priori probability of the ranging source failure. The bound for a ground subsystem’s monitor performance defined in Appendix B, 3.6.7.3.3.2 is illustrated in Figure D-11. GAEC-D equipment will use the 30-second differential corrections to form the position solution used for deviation guidance. The limits of the constraint region define the minimum Pmd that the ground subsystem must ensure for any single ranging source failure condition.

Note. — The example compliant Pmd in Figure D-11 is based on a hypothetical monitor with a threshold set to 0.8 m and monitor noise of 0.123 m. The curve is for illustration purposes only and does not represent the performance of any specific monitor design.

- 2) The second requirement constrains the conditional probability of the Pmd performance of the specified ranging source given the a-priori failure probability for the specific ranging source failure. The conditional probability bound, $P_{md} \times P_{apriori}$, for a ground subsystem’s monitor performance defined in Appendix B, 3.6.7.3.3.3 is illustrated in Figure D-12. The prior probability of each ranging source failure ($P_{apriori}$), used to evaluate compliance, should be the same value that is used in the analysis to show compliance with the bounding requirements for FAST C and D (see 7.5.3.1).

7.5.12.1 Verification of ground subsystem compliance with range domain monitoring requirements

Verifying that a ground system design complies with the monitor requirements provided in Appendix B, 3.6.7.3.3.2 and 3.6.7.3.3.3 is achieved by a combination of testing and analysis. The requirements take the form of a constraint on the probability of missed detection as a function of the size of an error in the corrected pseudo-range. The general process that may be used to verify that a specific monitor, included as part of a ground subsystem design, meets the specified performance is as follows:

- Identify the threat space for each fault mode to be considered. (The requirements in Appendix B, 3.6.7.3.3 apply to four specific fault modes). These fault modes (i.e. the threat space), which may be used for evaluating compliance with a ground subsystem design, are provided in 7.5.12.1.3.1 through 7.5.12.1.3.4. These fault modes and fault combinations constitute the threat space. These threat space

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 103

definitions represent what at least one State has found acceptable as an assumed threat space for each fault mode.

- Identify the airborne configuration space. The airborne system requirements introduce constraints on the design and performance of airborne equipment. These constraints define the range of critical airborne parameters of the configuration space for each fault mode and/or monitor that must be protected by the ground subsystem. For example, the bandwidth and correlator spacing of a compliant airborne receiver will conform to the requirements in sections 8.11.4 through 8.11.7.1. These are two of the critical parameters of the airborne configuration space for the satellite signal deformation fault mode. A critical airborne parameter directly influences how each point in the threat space translates to an error in the differentially corrected pseudo-range.

- An error analysis is done considering the specific monitor design under consideration given the full range of fault characteristics that comprise the threat space. For each characterized fault, the error that would be induced in the corrected pseudo-range (using the 30-second smoothed pseudo-ranges and pseudo-range corrections) is computed given the full range of critical airborne parameters that comprise the airborne configuration space.

- When assessing the compliance of a ground subsystem design, the performance is characterized by relevant statistical measures. Any monitor is subject to noise and therefore the performance may be characterized by the false detection rate and the missed detection probability. Both of these performance metrics are specified in the ground requirements in Appendix B by means of a not-to-exceed constraint. The missed detection probability performance is constrained by the requirements in Appendix B, 3.6.7.3.3.2 and 3.6.7.3.3.3. The false detection rate performance is constrained by the continuity requirements given in Appendix B, 3.6.7.1.3.2. It should be understood that the ground subsystem must meet all requirements in the Standards. It is possible that the performance of individual monitors may be further constrained by other requirements, such as the ground subsystem integrity risk requirement in Appendix B, 3.6.7.1.2.1.1.1. Ground station accuracy performance may have an impact on airborne and ground monitor performance. In the validation of requirement feasibility, a GAD C4 performance was assumed to account for instance for single reference receiver faults. Use of lower performance categories may have an availability or continuity impact and should be investigated in the design process.

7.5.12.1.1 Compliance of ground subsystem monitoring with continuity requirements. The compliance with the false detection rate (continuity) may be established based on collected real data combined with analysis and/or simulation. The required number of truly independent samples should be sufficient to adequately characterize the cumulative distribution function (CDF) of the monitor discriminator, which is compared to the threshold set for the monitor. The fault free noise CDF must be such that for the threshold set in the monitor the false detection probability is smaller than that required to support continuity. An allocation of the continuity to each monitor must be done with consideration given to the overall specified probability of false detection (Appendix B, 3.6.7.1.3.2). The achieved probability of false detection is determined by extrapolation of the observed trends in the measured CDF. Additionally, detection events in the ground system may be logged and if, over time, the false detection rates are not maintained at the required levels, thresholds may be adjusted as the result of a maintenance action to correct the problem.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 104

7.5.12.1.2 Compliance of ground subsystem monitoring with integrity requirements. The compliance with the missed detection probability (integrity risk) is typically established based on simulation and analysis. (Given the low allowed probability of observing actual faults, collection of enough real data to establish that the probability is met with any statistical significance is impossible.) The threat space for the fault mode is divided into discrete intervals across the relevant parameters that define the fault behavior. The total space of potential faults is represented by a multidimensional grid of discrete points that span the threat space. The airborne configuration space is also discretized i.e. represented by a multidimensional grid of discrete (critical parameter) points. A simulation is used to compute the expected pseudo-range error performance for each point in the threat space, each possible airborne configuration and the ground receiver function with the monitors. The worst-case error in the corrected pseudo-range is computed as a function of the discriminator value for the monitor addressing the threat (assuming no noise at this point). This also makes it possible to determine the discriminator value as a function of the worst-case error in the corrected pseudo-range (the inverse mapping). The missed detection probability is obtained by superimposing noise based on a conservative noise model (using an over bound of the CDF that was generated by the real data), on the discriminator determined from the worst-case differential range. This can be done either analytically or by simulation. The mapping from discriminator to worst-case error in the corrected pseudo-range and the noise levels applied may have further dependencies (for instance satellite elevation), and the established missed detection probability is therefore also a function of a set of parameters that constitute the detection parameter space which is divided into discrete intervals as well, i.e. represented by a multidimensional grid of discrete (detection parameter) points. The final missed detection probability is obtained by searching for the worst case when evaluating all the grid points in the detection parameter space.

7.5.12.1.3 Threat space and relevant airborne configuration space for each fault mode

7.5.12.1.3.1 Code carrier divergence threat

7.5.12.1.3.1.1 The code carrier divergence threat is a fault condition in a GPS satellite that causes the code and carrier of the broadcast signal to diverge excessively.

7.5.12.1.3.1.2 A code carrier divergence fault may cause a differential ranging error in one or both of the following cases: (1) the aircraft and ground filter designs are not identical, and (2) the aircraft and ground filters start at different times. Both of these cases can result in a difference between the transient responses of the filters in the presence of a CCD event.

The critical airborne parameters are:

- The time of initialization of the airborne smoothing filter relative to the fault onset.
- The smoothing filter type (fixed time constant 30 seconds or adjustable time constant equal to time from initialization up to 30 seconds and thereafter fixed).
 - The carrier code divergence rate monitoring required in airborne system for GAST D and the associated fault reaction.
 - The time period from initialization of the airborne smoothing filter to the incorporation of the measurement in the position solution.

7.5.12.1.3.2 Excessive acceleration threat

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 105

The excessive acceleration threat is a fault condition in a GPS satellite that causes the carrier (and code in unison) of the broadcast signal to accelerate excessively. The threat space is one-dimensional and corresponds to all possible accelerations including ramps and steps.

7.5.12.1.3.3 Ephemeris error threat

The ephemeris error threat is a fault condition that causes the broadcast ephemeris parameters to yield excessive satellite position errors perpendicular to the ground subsystem's line of sight to the satellite. The resultant differential range error is the satellite position error (true compared to broadcast ephemeris) multiplied by the distance between ground subsystem and airborne and scaled by the inverted distance to the satellite. It is bounded by the product of the P parameter (see 7.5.9) and the distance between the user and the ground subsystem. The critical airborne parameter for the ephemeris error threat is therefore the distance between the user and the ground subsystem. Satellite ephemeris faults are categorized into two types, A and B, based upon whether or not the fault is associated with a satellite manoeuvre. There are two subclasses of the type A fault, A1 and A2.

7.5.12.1.3.3.1 Ephemeris error threat type B

7.5.12.1.3.3.1.1 The type B threat occurs when the broadcast ephemeris data is anomalous, but no satellite manoeuvre is involved.

7.5.12.1.3.3.1.2 The GBAS ground subsystem can monitor against such faults by comparing current and prior ephemerides. One example of a type B fault: no manoeuvre occurs, an incorrect upload is sent to a satellite, and the satellite subsequently broadcasts an erroneous ephemeris.

7.5.12.1.3.3.2 Ephemeris error threat type A1 7.5.12.1.3.3.2.1 The type A1

threat occurs when the broadcast ephemeris data is anomalous following an announced and intentional satellite manoeuvre.

7.5.12.1.3.3.2.2 Prior ephemerides are of limited use in the detection of type A1 failures because of the intervening manoeuvre. The GBAS ground subsystem will need to monitor ranging data directly as part of ephemeris validation. One example of a type A1 fault: a satellite is set unhealthy, a manoeuvre is executed, an incorrect upload is sent to the satellite, the satellite is reset to healthy and subsequently broadcasts an erroneous ephemeris.

7.5.12.1.3.3.3 Ephemeris error threat type A2

7.5.12.1.3.3.3.1 The type A2 threat occurs when the broadcast ephemeris data is anomalous following an unannounced or unintentional satellite manoeuvre.

7.5.12.1.3.3.3.2 Prior ephemerides are of limited use in the detection of type A2 failures because of the intervening manoeuvre. The GBAS ground subsystem will need to monitor ranging data directly as part of ephemeris validation. One example of a type A2 fault: a satellite is set healthy, an intentional manoeuvre or unintentional thruster firing occurs, and the satellite continues to broadcast the pre-manoeuve (now erroneous) ephemeris.

7.5.12.1.3.4 Signal deformation threat

7.5.12.1.3.4.1 The signal deformation threat is a fault condition in the GPS satellite that causes the broadcast C/A code to be distorted so that the correlation peaks used for tracking in the airborne system and the ground system are deformed. The extent of the deformation depends on the receiver bandwidth and the resulting tracking error depends on where the correlator points used for code tracking are located (along the correlator peak).

7.5.12.1.3.4.2 The signal deformation monitoring threat space is defined in section 8. There are three fault types A, B, C.

7.5.12.1.3.4.3 Most satellites naturally show some degree of correlator peak deformation and these are referred to as natural (correlator measurement) biases. These natural biases may vary over time.

7.5.12.1.3.4.4 A fault condition (onset) will appear as a step in the raw (unfiltered) code measurement both in the airborne system and in the ground. If both systems had exactly the same front end (RF and IF filtering, sampling method), correlator type and correlator spacing the error would be the same in ground and air and no differential error would occur. But typically, that is not the case.

7.5.12.1.3.4.5 The step is filtered by the smoothing algorithm in the ground and in the airborne systems and the steady state differential error will gradually manifest itself in a 60 – 90 second time frame when using corrections from message Type 11 (or 200 – 300 seconds for message Type 1).

7.5.12.1.3.4.6 If a fault (A, B or C) occurs in a satellite it will take about 60 – 90 seconds before the steady state for the error and the monitor discriminator is reached. In essence the fault onset starts a race between the increasing differential error and the monitor discriminator as it moves towards the threshold. This is referred to as the transient state. If the range error reaches the limit that must be protected while the discriminator is not yet past the threshold with sufficient margin to guarantee the required detection probability, the requirement is not met. Both the steady state and the transient state performance must be evaluated.

7.5.12.1.3.4.7 The critical airborne parameters for the signal deformation threat are:

- The time period from initialization of the airborne smoothing filter to incorporation of the measurement in the position solution.
- The parameters that have constraints defined in the GAST D standard (Attachment B) including:
 - o Correlator type Early-Late (EL) or Double Delta (DD)
 - o Correlator spacing
 - o GPS signal bandwidth (from reception at antenna through RF, IF, and A/D conversion)
- Group delay (from reception at antenna through RF, IF, and A/D conversion)

7.5.12.1.3.4.8 Apart from the discrete choice of EL versus DD the configuration space is two-dimensional (correlator spacing and bandwidth). The filters implemented in the airborne system may be of different types (Butterworth, Chebychev, Elliptical, etc.). The group-delay constraints will exclude some of these filters. However, the possible variation in receiver design introduces additional dimensions that the ground subsystem manufacturer must consider. The filter types are part of the configuration space to be considered.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

7.5.13 Ground subsystem requirements and airworthiness performance assessment. Airworthiness certification of autoland systems, for use in Category II/III operations, requires an assessment of landing performance under fault-free and faulted conditions. More information, describing how the technical standards can be used to support an assessment, may be found in RTCA document DO-253D, “Minimum Operational Performance Requirements for Airborne Equipment using the Local Area Augmentation System”, Appendix J”.

7.5.13.1 *Estimating availability.* It may, in some cases, be necessary to estimate the expected availability for an airport or a runway end. Examples are cases where the mask angles are high or E_{IG} exceeds 2.75 m. When the maximum value of 2.75 m is established for the E_{IG}, this is based on availability simulations where conservative assumptions are used for the constellation and aircraft performance, and the target is to provide the GAST D service with an availability of 0.999 for Category III airports around the world. Therefore, the E_{IG} limit of 2.75 m guarantees an availability that is higher than 0.999 under the worst-case assumptions, when only the residual ionospheric component is considered. However, for many locations, the availability may still be within this limit for E_{IG} > 2.75 m. Also, Chapter 3, Table 3.7.2.4-1 specifies a range of availability requirements, and the service provider must assess which availability is needed for the operation in question. In case GAST D service is provided to an LTP where E_{IG} exceeds 2.75 m, no assumptions can be made on availability, and the service provider is then responsible for estimating the availability according to the guidance outlined below, making assumptions on airborne performance. The maximum allowable undetected airborne error in the position domain (maxE_v, maxE_l) as derived from the touchdown airworthiness requirements, can be assumed to be 10 m or higher.

7.5.13.2 In general, availability at a given approach can be estimated by taking into account the ground station parameters transmitted under normal conditions, to compute airborne VEB/LEB and VPL/LPL and to compare against VALs/LALs for a particular approach. The result of the airborne geometry screening is a separate component of the availability. For cases where E_{IG} exceeds 2.75 m, it is sufficient to consider the availability resulting from airborne geometry screening, which will drive availability rather than protection levels.

7.5.13.3 At a minimum, the duration of the simulation must consider all constellation states (24 hours for GPS). When taking additional probabilistic considerations into account, e.g. scintillation probability, longer simulation durations may be required.

7.5.13.4 VPL/LPL should be compared against VAL/LAL at 200 ft (or at the threshold if that is further away from the GBAS reference point).

7.5.13.5 VEB/LEB should be compared against VAL/LAL at 23 NM or wherever the approach is intended to start.

7.5.13.6 The constellation to be used is the standard expandable (27 SV) constellation, as defined in the *GPS Standard Positioning Service (SPS) Performance Standard, Fourth Edition* with N-1 and N-2 state probabilities as given in Table D-XX.

7.5.13.7 If the availability requirement is met under these conditions, no further analysis is required. If additional analysis is needed, a less conservative constellation can be used, e.g. a contemporary Yuma almanac. The same constellation state probabilities may be used, or, if possible, probabilities applicable to that constellation.

Table D-11. GPS constellation state probabilities

<i>GPS constellation state</i>	<i>N satellites operating</i>	<i>N-1</i>	<i>N-2</i>	<i>N-3</i>	<i>N-4</i>
Probability	0.95	0.035	0.015	0	0

7.5.13.8 The ground station parameters are those transmitted by the particular ground subsystem.

7.5.13.9 The assumptions for airborne parameters are:

- AAD B;
- aircraft speed: 160 kts;
- $\sigma_{\text{divg}} : 0$ (assumes smoothing filter steady state);
- $\sigma_{\text{noise}} : 0.15$ (worst-case within AAD B);
- MaxEv, MaxEL: 10 m;
- $\text{MaxS}_{\text{vert}} = \text{MaxEv} / E_R$;
- $\text{MaxS}_{\text{Lat}} = \text{MaxEL} / E_R$;
- $\text{MaxS}_{\text{vert}2} = \text{MaxEv} / \max(E_{IG})$;
- $\text{MaxS}_{\text{Lat}2} = \text{MaxEL} / \max(E_{IG})$;
- E_R is the maximum undetected pseudo-range error for the GAST D approach, either 1.6 m or EIG for the approach, whichever is larger; and
- the airborne receiver is capable of simultaneously tracking and continuously decoding the associated navigation data for at least 12 ranging sources.

7.5.14 GBAS signal-in-space time-to-alert. The GBAS signal-in-space time-to-alert (SIS TTA) is defined below within the context of GBAS based upon the TTA definition in Chapter 3, section 3.7.1. The GBAS SIS TTA is the maximum allowable time elapsed from the onset of an out-of-tolerance condition at the output of the fault-free aircraft GBAS receiver until the aircraft GBAS receiver annunciates the alert. This time is a never-to-be-exceeded limit and is intended to protect the aircraft against prolonged periods of guidance outside the lateral or vertical alert limits.

7.5.14.1 There are two allocations made to support the GBAS SIS TTA in the Standards.

- 1) The first allocation, the ground subsystem TTA for SIS requirements, limits the time it takes the ground subsystem to provide an indication that it has detected an out-of-tolerance situation considering the output of a fault-free GBAS receiver. The indication to the aircraft element is either: a) to broadcast Type 1 (and Type 11 if broadcast) or Type 101 messages indicating the condition (in accordance with Appendix B, 3.6.7.3.2.1), or b) terminate all VDB transmissions. The ground subsystem is allocated 3 seconds to take either action.

For airborne receivers using GAST C, at least one Type 1 message signaling the out-of-tolerance condition must be received by a fault-free airborne receiver within the message time out to meet the SIS TTA. For airborne receivers using GAST D at least one of each (Type 1 and Type 11) message with the same applicable modified z-count (and the same set of satellites) must be received by a fault-free airborne receiver within the message time out to meet the SIS TTA. Because shutting down the VDB may result in an exposure time longer than the SIS TTA for satellite faults, this option is recommended only under conditions where the VDB transmission does not meet its associated performance requirements (reference Appendix B, 3.6.7.3.1.1.).

In addition, for ground subsystems that support GAST D monitoring performance requirements, the ground subsystem is allocated only 1.5 seconds to detect a condition producing out-of-tolerance errors in 30-second corrected pseudo-ranges and to either exclude the ranging source measurements from the broadcast or mark them as invalid. This time-to-detect and broadcast is similar in definition, but not equivalent in function to

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 109

the ground subsystem TTA, as an out-of-tolerance condition in a single ranging source does not necessarily lead to out-of-tolerance guidance information.

- 2) The second allocation for the GBAS signal-in-space time-to-alert provides for the possible temporary loss of message reception. Airborne equipment operating with GAST C active will generate an alert if a Type 1 message is not received within 3.5 seconds when on the final stages of approach. When the airborne equipment is below 200 ft height above the runway threshold (HAT), airborne equipment operating with GAST D active will generate an alert or change the active service type if a set of Type 1 and Type 11 messages with the same modified z-count are not received within 1.5 seconds. Note that these time-outs will also dictate the achieved signal-in-space time-to-alert when the ground subsystem ceases VDB transmissions instead of broadcasting messages as an alert to the airborne equipment.

Requirements on how quickly the receiver outputs must be invalidated (so annunciating an alert), as well as additional conditions requiring the outputs to be indicated as invalid, are contained in RTCA DO-253D. For example, there is a requirement for the aircraft GBAS receiver position determination function to use the most recently received message content and reflect the message content in its outputs within 400 ms. The SIS TTA is defined by start and stop events at the same point in the aircraft. Any processing that is common to generating outputs under both normal conditions and alert conditions will not change the achieved SIS TTA. That is, this common period acts like a lag to both the start event and end event and does not affect the total exposure time to the aircraft. Within the GBAS receiver, the outputs under both of these conditions must meet the same latency requirement, so large differences are not expected. SIS TTA will differ from ground subsystem TTA by a value equal to the difference between receiver processing time and receiver time to invalidate outputs.

7.5.14.2 Table D-5C summarizes the time periods that contribute to the GBAS SIS TTA and the range of achieved TTA that can be expected.

7.5.14.3 Figure D-13 illustrates the nominal case with no missed messages and Figure D-14 illustrates the effect of missed messages for GAST D below 200 ft. Above 200 ft, the situation is similar, but the aircraft has a longer missed message allocation, as described above.

7.5.14.3.1 Figure D-14 illustrates the effect on the SIS TTA due to missed messages (upper half) and VDB termination (lower half) using the example of GAST D requirements below 200 ft. The upper time-line shows just two messages being missed, but the third is received, so operations can continue, unless the third message is indicating a fault condition that results in an alert from the receiver. The lower time-line shows the effect of the VDB terminating. The aircraft receiver invalidates its outputs after three messages are missed. The SIS TTA combines the ground TTA and the missed message allocation (See Table D-5B), but it is now displaced by the aircraft receiver processing time. Above 200 ft, the situation is similar, but the aircraft has a longer allocation, as described in RTCA DO-253D.

7.5.14.3.2 For SIS integrity, the diagram indicates that the SIS TTA starting point is where the fault-free airborne receiver outputs out-of-tolerance data. The SIS TTA end event is also at the output of the airborne receiver.

7.5.14.3.3 The start event of the ground subsystem's time-to-alert or time-to-detect and broadcast is the last bit of the first message (Type 1 and Type 11 message pair for GAST D) including the out-of-tolerance data. For ground equipment failures or termination of the VDB signal, this is the first message the ground subsystem broadcasts containing correction, integrity or path information that does not conform to the applicable integrity requirement (e.g. SIS integrity, ground subsystem integrity). For satellite failures, the requirements are out-of-tolerance once differential pseudo-range errors exceed the performance metrics detailed within a certain

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 110

requirement (e.g. Ranging Source Monitoring). Their end event is the last bit of the first message (message pair for GAST D) removing the out-of-tolerance data or flagging it invalid.

7.5.14.3.4 It should be noted that, while the Figure D-13 indicates that the SIS and ground subsystem TTAs reference different start and end points in time, an ANSP may assume that they are the same. A ground subsystem should be evaluated and certified with no credit or penalty for airborne receiver variations due to a specific, approved aircraft implementation. From the ground subsystem perspective, all received messages are assumed to be instantaneously applied or acted upon by the airborne receiver. This effectively results in equivalent SIS and ground subsystem TTA reference points from the ground subsystem's point of view.

7.5.15 Ground subsystem integrity risk for GAST D. Appendix B, 3.6.7.1.2.1.1.3 specifies a new ground subsystem integrity requirement relating to fail-safe design criteria. This integrity method will ensure that failures within the ground subsystem that might affect the stations functions and result in erroneous information are extremely improbable. The intent of this requirement is to specify the allowable risk that the ground subsystem would internally generate and cause erroneous information to be broadcast. Other requirements specify the required performance of the ground subsystem with respect to detection and mitigation of faults originating outside the ground subsystem (such as ranging source failures). This requirement relates to the probability that the ground subsystem fails to meet the intended function. The intended function for GBAS is defined in Chapter 3, 3.7.3.5.2. The functions listed in that section and their associated performance requirements characterize the intended function of the system.

Table D-12. Contributions to signal-in-space time-to-alert

<i>Integrity risk requirements and service types</i>	<i>Ground subsystem TTA [Note 1]</i>	<i>Message time-out in aircraft [Note 5]</i>	<i>Signal-in-space TTA (nominal) [Note 6]</i>	<i>Signal-in-space TTA (maximum) [Note 7]</i>
App B, 3.6.7.1.2.1.1.1 and 3.6.7.1.2.2.1 (GAST A,B,C)	3.0 s [Note 2]	3.5 s	3.0 s	6.0 s
App B, 3.6.7.1.2.1.1.2 and 3.6.7.1.2.2.1 (GAST D)	3.0 s [Notes 2 and 8]	3.5 s (above 200 ft HAT) 1.5 s (below 200 ft HAT)	3.0 s 3.0 s	6.0 s 4.0 s
App. B, 3.6.7.1.2.1.1.3 (GAST D)	1.5 s	3.5 s (above 200 ft HAT) 1.5 s (below 200 ft HAT)	1.5 s 1.5 s	4.5 s [Note 3] 2.5 s [Note 3]
App. B, 3.6.7.3.3 (GAST D)	1.5 s [Note 9]	3.5 s (above 200 ft HAT) 1.5 s (below 200 ft HAT)	1.5 s 1.5 s	4.5 s [Note 4] 2.5 s [Note 4]

Note 1.— These ground subsystem TTA requirements apply to a ground subsystem transmitting Type 1 messages. Ground subsystems transmitting Type 101 messages have a 5.5 s TTA as standardized in Appendix B, 3.6.7.1.2.1.2.1.2.

Note 2.— These times apply to excluding all ranging sources, marking all ranging sources as invalid in message Type 1 or the cessation of VDB transmission. When a single ranging source is marked invalid or excluded, it may or may not cause the aircraft receiver to generate an alert, depending on the role of that ranging source in the aircraft’s position solution.

Note 3.— This design requirement applies to the integrity of internal ground subsystem functions (excluding single reference receiver failures). This includes the ground subsystem ranging source monitoring capability. The table illustrates the exposure time for ground equipment failures that result in the transmission of non-compliant information and that are enunciated to the aircraft using the VDB transmission.

Note 4.— These requirements apply to the integrity monitoring for GNSS ranging sources. When a single ranging source is marked invalid or excluded, it may or may not cause the aircraft receiver to generate an alert, depending on the role of that ranging source in the aircraft’s position solution. The times listed in the table assume the ranging source was critical to determining the position solution.

Note 5.— The missed message time-out allocation starts with the last received message and not with the first missed message, so is 0.5 s longer than time added to the SIS time-to-alert.

Note 6.— If transmissions continue and there are no missed messages, the “nominal” column is relevant. This value includes the maximum ground subsystem contribution.

Note 7.— The maximum SIS TTA includes the maximum ground subsystem contribution and the possible temporary loss of message reception. When VDB transmissions cease, the maximum SIS TTA is relevant. This time is computed by adding the ground subsystem TTA and the airborne message time out minus 0.5 s (see Note 5).

Note 8.— Although these sections are related to FAST D and the maximum TTA values are larger than those historically associated with Category II/III operations, the TTA values in this line are not relevant for integrity to support Category II/III. These TTA values apply to the bounding conditions (see 7.5.3.1) and therefore are related to the total risk of fault-free error sources and faults exceeding the protection levels. For GAST D, the effects of malfunctions are addressed by the additional requirements in Appendix B, 3.6.7.1.2.1.1.3, Appendix B, 3.6.7.3.3 and additional airborne requirements as provided in RTCA DO-253D, for example the reference receiver fault monitor. These additional requirements are more constraining and enforce a shorter TTA that is appropriate for Category II/III operations. The existence of the longer TTA values in this line should not be interpreted to imply that errors near or exceeding the alert limit for up to these longer exposure times can occur with a probability greater than 1 x 10⁻⁹ in any landing.

Note 9.— This is “time to detect and broadcast”; the other ground system requirements apply in addition.

7.5.15.1 Verification of compliance with subsystem integrity risk for GAST D. Verification that a ground subsystem meets the integrity risk requirements of Appendix B, 3.6.7.1.2.1.1.3 would typically be accomplished

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 112

through a combination of analysis and appropriate safety-related design practices/processes. The overall process must ensure that failures within the ground subsystem that might affect the stations intended functions and result in erroneous information are extremely improbable. All ground subsystem component failure conditions must be shown to be sufficiently mitigated through either direct monitoring or through use of an acceptable design assurance development process (such as RTCA/DO-178 and RTCA/DO-254). The methodology should provide assurance of mitigation of component (HW, SW) failures. The integrity method of design assurance, applied in conjunction with fail-safe design concepts and other assurance actions (such as those in SAE ARP 4754) to detect and remove systematic errors in the design, provides safety assurance of the GAST D ground system. safety assurance guidance can be found in ICAO’s Safety Management Manual (SMM) (Doc 9859).

7.6 Continuity of service

7.6.1 Ground continuity and integrity designator. The ground continuity and integrity designator (GCID) provide a classification of GBAS ground subsystems. The ground subsystem meets the requirements of Category I precision approach or APV when GCID is set to 1. GCID 2, 3 and 4 are intended to support future operations with requirements that are more stringent than Category I operations. The GCID is intended to be an indication of ground subsystem status to be used when an aircraft selects an approach. It is not intended to replace or supplement an instantaneous integrity indication communicated in a Type 1 or Type 101 message. GCID does not provide any indication of the ground subsystem capability to support the GBAS positioning service.

7.6.2 Ground subsystem continuity of service. GBAS ground subsystems are required to meet the continuity specified in Appendix B to Chapter 3, 3.6.7.1.3 in order to support Category I precision approach and APV. GBAS ground subsystems that are also intended to support other operations through the use of the GBAS positioning service should support the minimum continuity required for terminal area operations, which is $1-10^{-4}$ /hour (Chapter 3, Table 3.7.2.4-1). When the Category I precision approach or APV required continuity ($1-8 \times 10^{-6}/15$ seconds) is converted to a per hour value it does not meet the $1-10^{-4}$ /hour minimum continuity requirement. Therefore, additional measures are necessary to meet the continuity required for other operations. One method of showing compliance with this requirement is to assume that airborne implementation uses both GBAS and ABAS to provide redundancy and that ABAS provides sufficient accuracy for the intended operation.

7.6.2.1 *Ground subsystem continuity of service for GAST D.* A ground segment that supports GAST D must meet the SIS continuity requirement ($1-8.0 \times 10^{-6}/15$ seconds) for a GAST A, B and C system but must also meet the continuity requirements specific to GAST D as defined in Appendix B, 3.6.7.1.3.2. The ground subsystem continuity is defined by two requirements. One is the continuity of the ground subsystem that includes failures of all components necessary for the VDB broadcast, including the reference receivers. It also includes loss of service due to integrity failures in the ground subsystem that result in alerts and monitor false alerts. The other allocation is the continuity associated with monitor fault-free detections. The reason for defining the ranging source monitor detections as a separate requirement is because the VDB broadcast portion includes all failures that result in the loss of the SIS, whereas the monitor contribution is related only to exclusion of individual satellites from the broadcast corrections. This does not necessarily result in a loss of the SIS by the airborne receiver. The requirement is defined on a per ranging source basis so that the ground design does not need to account for the actual number of satellites in view or the number considered critical to the user for a specific approach. It is the responsibility of the airborne user to demonstrate the overall continuity achieved when considering the contribution of the satellites and the airborne monitors.

7.7 GBAS channel selection

7.7.1 Channel numbers are used in GBAS to facilitate an interface between aircraft equipment and the signal-in-space that is consistent with interfaces for ILS and MLS. The cockpit integration and crew interface for GBAS may be based on entry of the 5-digit channel number. An interface based on approach selection through a flight management function similar to current practice with ILS is also possible. The GBAS channel number may be

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 113

stored in an on-board navigation database as part of a named approach. The approach may be selected by name and the channel number can automatically be provided to the equipment that must select the appropriate GBAS approach data from the broadcast data. Similarly, the use of the GBAS positioning service may be based on the selection of a 5-digit channel number. This facilitates conducting operations other than the approaches defined by the FAS data. To facilitate frequency tuning, the GBAS channel numbers for neighbouring GBAS ground subsystems supporting positioning service may be provided in the Type 2 message additional data block 2.

7.7.2 A channel number in the range from 20 001 to 39 999 is assigned when the FAS data are broadcast in the Type 4 message. A channel number in the range from 40 000 to 99 999 is assigned when the FAS data associated with an APV are obtained from the on-board database.

7.7.3 Every FAS data block uplinked in a Type 4 message will be associated with a single 5-digit channel number regardless of whether or not the approach is supported by multiple approach service types. For approaches that are supported by multiple approach service types, the approach performance designator field in the Type 4 message is used to indicate the most demanding approach service type supported by the ground subsystem for any specific approach.

7.8 Reference path data selector and reference station data selector

A mapping scheme provides a unique assignment of a channel number to each GBAS approach. The channel number consists of five numeric characters in the range 20 001 to 39 999. The channel number enables the GBAS airborne subsystem to tune to the correct frequency and select the final approach segment (FAS) data block that defines the desired approach. The correct FAS data block is selected by the reference path data selector (RPDS), which is included as part of the FAS definition data in a Type 4 message. Table D-6 shows examples of the relationship between the channel number, frequency and RPDS. The same mapping scheme applies to selection of the positioning service through the reference station data selector (RSDS). The RSDS is broadcast in the Type 2 message and allows the selection of a unique GBAS ground subsystem that provides the positioning service. For GBAS ground subsystems that do not provide the positioning service and broadcast the additional ephemeris data, the RSDS is coded with a value of 255. All RPDS and RSDS broadcast by a ground subsystem must be unique on the broadcast frequency within radio range of the signal. The RSDS value must not be the same as any of the broadcast RPDS values.

7.9 Assignment of RPDS and RSDS by service provider

RPDS and RSDS assignments are to be controlled to avoid duplicate use of channel numbers within the protection region for the data broadcast frequency. Therefore, the GBAS service provider has to ensure that an RPDS and RSDS are assigned only once on a given frequency within radio range of a particular GBAS ground subsystem. Assignments of RPDS and RSDS are to be managed along with assignments of frequency and time slots for the VHF data broadcast.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

Table D-13. Channel assignment examples

<i>Channel number (N)</i>	<i>Frequency in MHz (F)</i>	<i>Reference path data selector (RPDS) or Reference station data selector (RSDS)</i>
20 001	108.025	0
20 002	108.05	0
20 003	108.075	0
....
20 397	117.925	0
20 398	117.95	0
20 412 (Note)	108.025	1
20 413	108.05	1
....

Note.— Channels between 20 398 and 20 412 are not assignable because the channel algorithm maps them to frequencies outside the range of 108.025 MHz and 117.950 MHz. A similar “gap” in the channel assignments occurs at each RPDS transition.

7.10 GBAS identification

The GBAS identification (ID) is used to uniquely identify a GBAS ground subsystem broadcasting on a given frequency within the coverage region of the GBAS. The aircraft will navigate using data broadcast from one or more GBAS broadcast stations of a single GBAS ground subsystem (as identified by a common GBAS identification).

7.11 Final approach segment (FAS) path

7.11.1 FAS path is a line in space defined by the landing threshold point/fictitious threshold point (LTP/FTP), flight path alignment point (FPAP), threshold crossing height (TCH) and glide path angle (GPA). These parameters are determined from data provided in a FAS data block within a Type 4 message or in the on-board database. The relationship between these parameters and the FAS path is illustrated in Figure D-6.

7.11.1.1 FAS data blocks for SBAS and some GBAS approaches are held within a common onboard database supporting both SBAS and GBAS. ANSPs are responsible for providing the FAS data to support APV procedures when the Type 4 message is not broadcast. These data comprise the parameters contained within the FAS block, the RSDS, and associated broadcast frequency. The FAS block for a particular approach procedure is described in Appendix B, 3.6.4.5.1 and Table B-66.

7.11.2 FAS path definition

7.11.2.1 Lateral orientation. The LTP/FTP is typically at or near the runway threshold. However, to satisfy operational needs or physical constraints, the LTP/FTP may not be at the threshold. The FPAP is used in conjunction with the LTP/FTP to define the lateral reference plane for the approach. For a straight-in approach aligned with the runway, the FPAP will be at or beyond the stop end of the runway. The FPAP is not placed before the stop end of the runway.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 115

7.11.2.2 Length offset. The length offset defines the distance from the end of the runway to the FPAP. This parameter is provided to enable the aircraft equipment to compute the distance to the end of the runway. If the length offset is not set to appropriately indicate the end of the runway relative to the FPAP, the service provider should ensure the parameter is coded as “not provided”.

7.11.2.3 Vertical orientation. Local vertical for the approach is defined as normal to the WGS-84 ellipsoid at the LTP/FTP and may differ significantly from the local gravity vector. The local level plane for the approach is defined as a plane perpendicular to the local vertical passing through the LTP/FTP (i.e. tangent to the ellipsoid at the LTP/FTP). The datum crossing point (DCP) is a point at a height defined by TCH above the LTP/FTP. The FAS path is defined as a line with an angle (defined by the GPA) relative to the local level plane passing through the DCP. The GPIIP is the point where the final approach path intercepts the local level plane. The GPIIP may actually be above or below the runway surface depending on the curvature of the runway.

7.11.3 “ILS look-alike” deviation computations. For compatibility with existing aircraft designs, it is desirable for aircraft equipment to output guidance information in the form of deviations relative to a desired flight path defined by the FAS path. The Type 4 message includes parameters that support the computation of deviations that are consistent with typical ILS installations.

7.11.3.1 Lateral deviation definition. Figure D-6 illustrates the relationship between the FPAP and the origin of the lateral angular deviations. The course width parameter and FPAP are used to define the origin and sensitivity of the lateral deviations. By adjusting the location of the FPAP and the value of the course width, the course width and sensitivity of a GBAS can be set to the desired values. They may be set to match the course width and sensitivity of an existing ILS or MLS. This may be necessary, for example, for compatibility with existing visual landing aids.

7.11.3.1.1 Lateral deviation reference. The lateral deviation reference plane is the plane that includes the LTP/FTP, FPAP and a vector normal to the WGS-84 ellipsoid at the LTP/FTP. The rectilinear lateral deviation is the distance of the computed aircraft position from the lateral deviation reference plane. The angular lateral deviation is a corresponding angular displacement referenced to the GBAS azimuth reference point (GARP). The GARP is defined to be beyond the FPAP along the procedure centre line by a fixed offset value of 305 m (1 000 ft).

7.11.3.1.2 Lateral displacement sensitivity. The lateral displacement sensitivity is determined by the aircraft equipment from the course width provided in the FAS data block. The service provider is responsible for setting the course width parameter to a value that results in the appropriate angle for full scale deflection (i.e. 0.155 DDM or 150 μ A) taking into account any operational constraints.

7.11.3.2 Vertical deviations. Vertical deviations are computed by the aircraft equipment with respect to a GBAS elevation reference point (GERP). The GERP may be at the GPIIP or laterally offset from the GPIIP by a fixed GERP offset value of 150 m. Use of the offset GERP allows the glide path deviations to produce the same hyperbolic effects that are normal characteristics of ILS and MLS (below 200 ft). The decision to offset the GERP or not is made by the aircraft equipment in accordance with requirements driven by compatibility with existing aircraft systems. Service providers should be aware that users may compute vertical deviations using a GERP which is placed at either location. Sensitivity of vertical deviations is set automatically in the aircraft equipment as a function of the GPA. The specified relationship between GPA and the full-scale deflection (FSD) of the vertical deviation sensitivity is: $FSD = 0.25 * GPA$. The value 0.25 is the same as for MLS (Attachment G, 7.4.1.2) and differs slightly from the nominal value of 0.24 recommended for ILS (Chapter 3, section 3.1.5.6.2). However, the value specified is well within the tolerances recommended for ILS (0.2 to 0.28). Therefore, the resulting sensitivity is equivalent to the glide path displacement sensitivity provided by a typical ILS.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 116

7.11.4 Approaches not aligned with the runway. Some operations may require the definition of a FAS path that is not aligned with the runway center line as illustrated in Figure D-7. For approaches not aligned with the runway, the LTP/FTP may or may not lie on the extended runway center line. For this type of approach length offset is not meaningful and should be set to “not provided”.

7.11.5 SBAS service provider. A common format is used for FAS data blocks to be used by both GBAS and SBAS. The SBAS service provider ID field identifies which SBAS system(s) may be used by an aircraft that is using the FAS data during an approach. The GBAS service provider may inhibit use of the FAS data in conjunction with any SBAS service. For precision approaches based on GBAS this field is not used, and it can be ignored by aircraft GBAS equipment.

7.11.6 Approach identifier. The service provider is responsible for assigning the approach identifier for each approach. The approach identification should be unique within a large geographical area. Approach identifications for multiple runways at a given aerodrome should be chosen to reduce the potential for confusion and misidentification. The approach identification should appear on the published charts that describe the approach. The first letter of the approach identifier is used in the authentication protocols for GBAS. Ground stations that support the authentication protocols must encode the first character of the identifier for all approaches supported from the set of letters {A X Z J C V P T} as described in Appendix B, section 3.6.7.4.1.4. This enables airborne equipment (that supports the authentication protocols) to determine which slots are assigned to the ground station and therefore to subsequently ignore reception of data broadcast in slots not assigned to the selected ground station. For ground stations that do not support the authentication protocols, the first character of the approach identifier may be assigned any character except those in the set {A X Z J C V P T}.

7.12 Airport siting considerations

7.12.1 The installation of a GBAS ground subsystem involves special considerations in choosing prospective sites for the reference receiver antennas and the VDB antenna(s). In planning antenna siting, ICAO Annex 14 obstacle limitation requirements must be met.

7.12.2 Locating reference receiver antennas. The site should be selected in an area free of obstructions, so as to permit the reception of satellite signals at elevation angles as low as possible. In general, anything masking GNSS satellites at elevation angles higher than 5 degrees will degrade system availability.

7.12.2.1 The antennas for the reference receivers should be designed and sited to limit multipath signals that interfere with the desired signal. Mounting antennas close to a ground plane reduces long-delay multipath resulting from reflections below the antenna. Mounting height should be sufficient to prevent the antenna being covered by snow, or being interfered with by maintenance personnel or ground traffic. The antenna should be sited so that any metal structures, such as air vents, pipes and other antennas are outside the near-field effects of the antenna.

7.12.2.2 Besides the magnitude of the multipath error at each reference receiver antenna location, the degree of correlation must also be considered. Reference receiver antennas should be located in places that provide independent multipath environments.

7.12.2.3 The installation of each antenna should include a mounting that will not flex in winds or under ice loads. Reference receiver antennas should be located in an area where access is controlled. Traffic may contribute to error due to multipath or obstruct view of satellites from the antennas.

7.12.3 Locating the VDB antenna. The VDB antenna should be located so that an unobstructed line-of-sight exists from the antenna to any point within the coverage volume for each supported FAS. Consideration should

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 117

also be given to ensuring the minimum transmitter-to-receiver separation so that the maximum field strength is not exceeded. In order to provide the required coverage for multiple FASs at a given airport, and in order to allow flexibility in VDB antenna siting, the actual coverage volume around the transmitter antenna may need to be considerably larger than that required for a single FAS. The ability to provide this coverage is dependent on the VDB antenna location with respect to the runway and the height of the VDB antenna. Generally speaking, increased antenna height may be needed to provide adequate signal strength to users at low altitudes, but may also result in unacceptable multipath nulls within the desired coverage volume.

A suitable antenna height trade-off must be made based on analysis, to ensure the signal strength requirements are met within the entire volume. Consideration should also be given to the effect of terrain features and buildings on the multipath environment.

7.12.3.1 In order to ensure that the maximum field strength requirements defined in Chapter 3, 3.7.3.5.4.4 are not violated, VDB transmitters should not be located any closer than 80 m to where aircraft are approved to operate based on published procedures using GBAS or ILS guidance information. This applies to aircraft on final approach, departure, and on runways. The 80-metre separation applies to the slant range distance between VDB transmit antennas and the aircraft antenna position. For aircraft on the runway the maximum deviation from the centre line can be assumed to be 19 m. In regions prior to runway thresholds, the maximum lateral course angular deviation from the extended centre line on final approach is plus and minus one sixth of the full course width, which is nominally 210 m (± 105 m (± 350 ft)) at threshold. The origin of the lateral course should be assumed to be the GBAS GARP, or the ILS localizer, as appropriate. The maximum vertical deviation is one half of the full-scale deflection from the glide path, where full scale deflection is calculated as ± 0.25 times the glide path angle. The origin of the glide path should be assumed to be the GPIIP. See 7.11.3 for further guidance on lateral and vertical course width deviation sensitivity.

7.12.4 Use of multiple transmit antennas to improve VDB coverage. For some GBAS installations, constraints on antenna location, local terrain or obstacles may result in ground multipath and/or signal blockage that make it difficult to provide the specified field strength at all points within the coverage area. Some GBAS ground facilities may make use of one or more additional antenna systems, sited to provide signal path diversity such that collectively they meet the coverage requirements.

7.12.4.1 Whenever multiple antenna systems are used, the antenna sequence and message scheduling must be arranged to provide broadcasts at all points within the coverage area that adhere to the specified minimum and maximum data broadcast rates and field strengths, without exceeding the receiver's ability to adapt to transmission-to-transmission variations in signal strength in a given slot. To avoid receiver processing issues concerning lost or duplicated messages, all transmissions of the Type 1 or Type 101 message, or linked pair of Type 1 or Type 101 messages for a given measurement type within a single frame need to provide identical data content.

7.12.4.2 One example of the use of multiple antennas is a facility with two antennas installed at the same location but at different heights above the ground plane. The heights of the antennas are chosen so that the pattern from one antenna fills the nulls in the pattern of the other antenna that result from reflections from the ground plane. The GBAS ground subsystem alternates broadcasts between the two antennas, using one or two assigned slots of each frame for each antenna. Type 1 or Type 101 messages are broadcast once per frame, per antenna. This allows for reception of one or two Type 1 or Type 101 messages per frame, depending on whether the user is located within the null of one of the antenna patterns. Type 2 and 4 messages are broadcast from the first antenna in one frame, then from the second antenna in the next frame. This allows for reception of one each of the Type 2 and 4 messages per one or two frames, depending on the user location.

7.13 Definition of lateral and vertical alert limits

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 118

7.13.1 The lateral and vertical alert limits for Category I precision approach are computed as defined in Appendix B, Tables B-68 and B-69. In these computations the parameters D and H have the meaning shown in Figure D-8.

7.13.2 The vertical alert limit for Category I precision approach is scaled from a height of 60 m (200 ft) above the LTP/FTP. For a procedure designed with a decision height of more than 60 m (200 ft), the VAL at that decision height will be larger than the broadcast FASVAL.

7.13.3 The lateral and vertical alert limits for APV procedures associated with channel numbers 40 001 to 99 999 are computed in the same manner as for APV procedures using SBAS as given in Attachment D, 3.2.8.

7.14 Monitoring and maintenance actions

7.14.1 Specific monitoring requirements or built-in tests may be necessary and should be determined by individual ANSP. Since the VDB signal is critical to the operation of the GBAS broadcast station, any failure of the VDB to successfully transmit a usable signal within the assigned slots and over the entire coverage area is to be corrected as soon as possible. Therefore, it is recommended that the following conditions be used as a guide for implementing a VDB monitor:

- a) Power. A significant drop in power is to be detected within 3 seconds.
- b) Loss of message type. The failure to transmit any scheduled message type(s). This could be based on the failure to transmit a unique message type in succession, or a combination of different message types.
- c) Loss of all message types. The failure to transmit any message type for a period equal to or greater than 3 seconds will be detected.

7.14.2 Upon detection of a failure, and in the absence of a backup transmitter, termination of the VDB service should be considered if the signal cannot be used reliably within the coverage area to the extent that aircraft operations could be significantly impacted. Appropriate actions in operational procedures are to be considered to mitigate the event of the signal being removed from service. These would include dispatching maintenance specialists to service the GBAS VDB or special ATC procedures. Additionally, maintenance actions should be taken, when possible, for all built-in test failures to prevent loss of GBAS service.

7.15 Examples of VDB messages

7.15.1 Examples of the coding of VDB messages are provided in Tables D-7 through D-10. The examples illustrate the coding of the various application parameters, including the cyclic redundancy check (CRC) and forward error correction (FEC) parameters, and the results of bit scrambling and D8PSK symbol coding. The engineering values for the message parameters in these tables illustrate the message coding process, but are not necessarily representative of realistic values.

7.15.2 Table D-7 provides an example of a Type 1 VDB message. The additional message flag field is coded to indicate that this is the first of two Types 1 messages to be broadcast within the same frame. This is done for illustration purposes; a second Type 1 message is not typically required, except to allow broadcast of more ranging source corrections than can be accommodated in a single message.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 119

7.15.3 Table D-7A provides an example of a Type 101 VDB message. The additional message flag field is coded to indicate that this is the first of two Types 101 messages to be broadcast within the same frame. This is done for illustration purposes; a second Type 101 message is not typically required, except to allow broadcast of more ranging source corrections than can be accommodated in a single message.

7.15.4 Table D -8 provides examples of a Type 1 VDB message and a Type 2 VDB message coded within a single burst (i.e. two messages to be broadcast within a single transmission slot). The additional message flag field of the Type 1 message is coded to indicate that it is the second of two Types 1 messages to be broadcast within the same frame. The Type 2 message includes additional data block 1. Table D-8A provides an example of Type 1 and Type 2 messages with additional data blocks 1 and 2.

7.15.4.1 Table D-8B provides an example of Type 2 messages with additional data blocks 1 and 4 coded within a single burst with a Type 3 message that is used to fill the rest of the time slot.

7.15.5 Table D-9 provides an example of a Type 4 message containing two FAS data blocks.

7.15.6 Table D-10 provides an example of a Type 5 message. In this example, source availability durations common to all approaches are provided for two ranging sources. Additionally, source availability durations for two individual approaches are provided: the first approach has two impacted ranging sources and the second approach has one impacted ranging source. The Type 2 message includes additional data block 1.

7.16 GBAS survey accuracy

The standards for the survey accuracy for NAVAIDs are contained in ICAO Annex -14 — *Aerodromes*. In addition, the *Manual of the World Geodetic System 1984 (WGS-84)* (ICAO Doc 9674) provides guidance on the establishment of a network of survey control stations at each aerodrome and how to use the network to establish WGS-84 coordinates. Until specific requirements are developed for GBAS, the ICAO Annex -14 survey accuracy requirements for NAVAIDs located at the aerodrome apply to GBAS.

The recommendation contained in Appendix B to Chapter 3, 3.6.7.2.3.4, for the survey accuracy of the GBAS reference point is intended to further reduce the error in the WGS-84 position calculated by an airborne user of the GBAS positioning service to a value smaller than that established by the requirements of Appendix B to Chapter 3, 3.6.7.2.4.1 and 3.6.7.2.4.2, in the GBAS standards and to enhance survey accuracy compared to that specified in ICAO Annex 14. The integrity of all aeronautical data used for GBAS is to be consistent with the integrity requirements in Chapter 3, Table 3.7.2.4-1.

7.17 Type 2 message additional data blocks

7.17.1 The Type 2 message contains data related to the GBAS facility such as the GBAS reference point location, the GBAS continuity and integrity designator (GCID) and other pertinent configuration information. A method for adding new data to the Type 2 message has been devised to allow GBAS to evolve to support additional service types. The method is through the definition of new additional data blocks that are appended to the Type 2 message. In the future, more additional data blocks may be defined. Data blocks 2 through 255 have variable length and may be appended to the message after additional data block 1 in any order.

7.17.2 Type 2 message additional data block 1 contains information related to spatial decorrelation of errors and information needed to support selection of the GBAS positioning service (when provided by a given ground station).

7.17.3 Type 2 message additional data block 2 data may be used in GRAS to enable the GRAS airborne subsystem to switch between GBAS broadcast stations, particularly if the GBAS broadcast stations utilize

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

different frequencies. Additional data block 2 identifies the channel numbers and locations of the GBAS broadcast station currently being received and other adjacent or nearby GBAS broadcast stations.

7.17.4 Type 2 message additional data block 3 is reserved for future use.

7.17.5 Type 2 message additional data block 4 contains information necessary for a ground station that supports the authentication protocols. It includes a single parameter which indicates which slots are assigned to the ground station for VDB transmissions. Airborne equipment that supports the authentication protocols will not use data unless it is transmitted in the slots indicated by the slot group definition field in the MT 2 ADB 4.

Table D-14. Example of a Type 1 VDB message

<p>Notes.—</p> <ol style="list-style-type: none"> The rightmost bit is the LSB of the binary parameter value and is the first bit transmitted or sent to the bit scrambler. All data fields are sent in the order specified in the table. This field is coded in hexadecimal with the first bit to be sent to the bit scrambler as its MSB. The first character represents a single bit. In this example fill bits are not scrambled. This field represents the phase, in units of $\pi/4$ (e.g. a value of 5 represents a phase of $5\pi/4$ radians), relative to the phase of the first symbol.

Notes:—					
1. The rightmost bit is the LSB of the binary parameter value and is the first bit transmitted or sent to the bit scrambler. All data fields are sent in the order specified in the table.					
2. This field is coded in hexadecimal with the first bit to be sent to the bit scrambler as its MSB. The first character represents a single bit.					
3. In this example, fill bits are not scrambled.					
4. This field represents the phase, in units of π/4 (e.g. a value of 5 represents a phase of 5π/4 radians), relative to the phase of the first symbol.					

Table D-18. Example of a Type 2 message containing data blocks 1, 3 and 4 and a Type 3 message to fill the remainder of the slot

All data fields are sent in the order specified in the table. This field is coded in hexadecimal with the first bit to be sent to the bit scrambler as its MSB. The first character represents a single bit. Symbols are represented by their differential phase with respect to the first symbol of the message, in units of $\pi/4$ (e.g. a value of 5 represents a phase of $5\pi/4$ radians) relative to the first symbol. 					

Table D-21. Example of a Type 11 VDB message

Notes:—

- The rightmost bit is the LSB of the binary parameter value and is the first bit transmitted or sent to the bit scrambler. All data fields are sent in the order specified in the table.
- This field is coded in hexadecimal with the first bit to be sent to the bit scrambler as its MSB. The first character represents a single bit.
- In this example fill bits are not scrambled.
- This field represents the phase, in units of π/4 (e.g. a value of 5 represents a phase of 5 π/4 radians), relative to the phase of the first symbol.

7.18 Type 101 message

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 138

Type 101 message is an alternative to Type 1 message developed to fit the specific needs of GRAS systems. The primary difference in the contents and application of these two message types is two-fold: (a) Type 101 message has a larger available range for $\sigma_{pr\ gnd}$ values and (b) ground subsystem time- to-alert is larger for a system broadcasting Type 101 messages. The first condition would typically occur in a system where a broadcast station covers a large area, such that decorrelation errors increase the upper limit of the pseudo-range correction errors. The second condition may be typical for systems where a central master station processes data from multiple receivers dispersed over a large area.

7.19 Airborne processing for GBAS approach service types

Note. — In order to ensure the required performance and functional objectives for GAST D are achieved, it is necessary for the airborne equipment to meet defined performance and functional standards. The relevant minimum operational performance standards (MOPS) are detailed in RTCA DO-253D.

7.19.1 *Differential position solution for the GBAS positioning service.* The position solution used to provide position, velocity and time outputs is based on 100-second smoothed pseudo-ranges corrected with corrections obtained from Message Type 1 or Message Type 101.

7.19.2 *Differential position solution for approach service GAST A, B and C.* When the active approach service type is A, B or C, the position solution used to generate deviations is based on 100-second smoothed pseudo-ranges corrected with corrections obtained from Message Type 1 or Message Type 101. The projection matrix, S , used to compute the position solution (Appendix B, 3.6.5.5.1.1.2) is computed based on \square_i computed using $\square_{pr_gnd}[i]$ from Message Type 1 or Message Type 101 and $\sigma_{iono,i}$ based on $\square_{vert_iono_gradient}$ from Message Type 2.

7.19.3 *Differential position solutions for approach service GAST D.* When GAST D is the active approach service type, the airborne equipment will compute two different position solutions, one based on 30-second smoothed pseudo-ranges and the other based on 100-second smoothed pseudo-ranges. The following characterizes the standard processing required by the MOPS:

- a) the position solution used to develop deviations is based on 30-second smoothed pseudo-ranges corrected with corrections obtained from Message Type 11;
- b) the projection matrix, S , used for both position solutions is computed based on $\square_{w,i}$ computed using $\square_{pr_gnd_30s}$ from Message Type 11 and $\square_{iono,i}$ based on $\square_{vert_iono_gradient_D}$ from Message Type 2 Additional Data Block 3;
- c) a second position solution is computed using the projection matrix from b) and the 100-second smoothed pseudo-ranges corrected with corrections obtained from Message Type 1; and
- d) both position solutions are based on the same set of satellites as used for the position solution defined in a) above.

Additional information regarding the intended use of these dual position solutions is given in 7.5.6.1 of this attachment.

7.20 Type 11 message

A Type 11 message is required for FAST D ground subsystems. The Type 11 message contains differential corrections derived from pseudo-range data that has been carrier smoothed with a time constant of 30 seconds. The Type 11 message also includes alternative parameters for integrity bounding and for optimal weighting of measurements. Additional information regarding the standard processing of parameters in the Type 11 message is given in 7.19.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 139

7.21 Slot occupancy

The slot occupancy requirement in Appendix B, 3.6.7.4.1.3 is for ground subsystems that support authentication. The slot occupancy is the length of a burst divided by the length of a single time slot. In more detail and expressed in number of bits: $slot\ occupancy = (88\ bits + up\ to\ 1\ 776\ bits\ application\ data + 57\ to\ 59\ bits\ for\ application\ FEC,\ fill\ bits\ and\ ramp\ down) / 1\ 968.75\ bits$

The numerator in the formula sums all bits that are included in a single burst of the ground subsystem. These are the first 88 bits from ramp up to training sequence FEC, up to 1 776 application data bits, 48 application FEC bits, 0 to 2 fill bits and 9 bits for ramp down. For the denominator 1 968.75 bits are

8. Signal quality monitor (SQM) design

8.1 The objective of the signal quality monitor (SQM) is to detect satellite signal anomalies in order to prevent aircraft receivers from using misleading information (MI). MI is an undetected aircraft pseudo-range differential error greater than the maximum error (MERR) that can be tolerated. These large pseudo-range errors are due to C/A code correlation peak distortion caused by satellite payload failures. If the reference receiver used to create the differential corrections and the aircraft receiver have different measurement mechanizations (i.e. receiver bandwidth and tracking loop correlator spacing), the signal distortion affects them differently. The SQM must protect the aircraft receiver in cases when mechanizations are not similar. SQM performance is further defined by the probability of detecting a satellite failure and the probability of incorrectly annunciating a satellite failure.

8.2 The signal effects that might cause a GBAS or SBAS to output MI can be categorized into three different effects on the correlation function as follows:

- a) Dead zones: If the correlation function loses its peak, the receiver's discriminator function will include a flat spot or dead zone. If the reference receiver and aircraft receiver settle in different portions of this dead zone, MI can result.
- b) False peaks: If the reference receiver and aircraft receiver lock to different peaks, MI could exist.
- c) Distortions: If the correlation peak is misshapen, an aircraft that uses a correlator spacing other than the one used by the reference receivers may experience MI.

8.3 The threat model proposed for use in assessment of SQM has three parts that can create the three correlation peak pathologies listed above.

8.4 Threat Model A consists of the normal code signal except that all the positive chips, and positive/negative sub-carrier chips for Galileo E1-C signal and BDS B1C_pilot signal, have a falling edge that leads or lags relative to the correct end-time for that chip. This threat model is associated with a failure in the navigation data unit (NDU), the digital partition of a satellite. The occurrences of Threat Model A on GPS L1 C/A and on GPS L5 Q5 signals are independent events. If overlapping in time, the signs and sizes of leads and lags may be different on L1 C/A and L5 Q5 signals.

8.4.1 Threat Model A for GPS has a single parameter Δ , which is the lead ($\Delta < 0$) or lag ($\Delta > 0$) expressed in microseconds. The range for this parameter is $-0.12 \leq \Delta \leq 0.12$ for the L1 C/A code signal. The range for this parameter is $-0.1 \leq \Delta \leq 0.1$ for the GPS L5 Q5 signal. Threat Model A for GLONASS has a single parameter Δ , which is the lead ($\Delta < 0$) or lag ($\Delta > 0$) expressed in microseconds. The range for this parameter is $-0.22 \leq \Delta \leq 0.22$ for GLONASS L1OF signal. The range for this parameter is $-0.1 \leq \Delta \leq 0.1$ for GLONASS L1OC signal and $-0.1 \leq \Delta \leq 0.1$ for GLONASS L3OC. Threat Model A for Galileo has a single parameter Δ , which is the lead ($\Delta < 0$) or lag ($\Delta > 0$) expressed in microseconds. The range for this parameter is $-0.12 \leq \Delta \leq 0.12$

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 140

for Galileo E1-C signal. The range for this parameter is $-0.1 \leq \Delta \leq 0.1$ for Galileo E5a-Q signal. Threat Model A for BDS has a single parameter Δ , which is the lead ($\Delta < 0$) or lag ($\Delta > 0$) expressed in microseconds. The range for this parameter is $-0.05 \leq \Delta \leq 0.05$

8.4.2 Within this range, threat Model A generates the dead zones described above. (Waveforms with lead need not be tested, because their correlation functions are simply advances of the correlation functions for lag; hence, the MI threat is identical.)

8.5 Threat Model B introduces amplitude modulation and models degradations in the analog section of the core constellation satellite. More specifically, it consists of the output from a second order system when the nominal C/A code baseband signal is the input. Threat Model B assumes that the degraded satellite subsystem can be described as a linear system dominated by a pair of complex conjugate poles. These poles are located at $\sigma \pm j2\pi f_d$, where σ is the damping factor in 10^6 nepers/second and f_d is the resonant frequency with units of 10^6 cycles/second.

8.5.1 The unit step response of a second order system is given by:

$$e(t) = \begin{cases} 0 & t \leq 0 \\ 1 - \exp(-\sigma t) \left[\cos \omega_d t + \frac{\sigma}{\omega_d} \sin \omega_d t \right] & t \geq 0 \end{cases}$$

$$\text{where } \omega_d = 2\pi f_d.$$

8.5.2 Threat Model B for GPS corresponding to second order anomalies uses the following ranges for the parameters, f_d and σ :

$$\Delta = 0; 4 \leq f_d \leq 17; \text{ and } 0.8 \leq \sigma \leq 8.8.$$

The occurrence of Threat Model A on the GPS L1 C/A signal, the occurrence of Threat Model B on GPS L1 C/A signal, the occurrence of Threat Model A on the GPS L5 Q5 signal and the occurrence of Threat Model B on the GPS L5 Q5 signal are independent events. The parameters characterizing the leads, lags, ringing frequency f_d , and decay parameter σ are not constrained to be the same size or sign on GPS L1 C/A and GPS L5 Q5 signals.

Threat Model B for GLONASS corresponding to second order anomalies uses the following ranges for the parameters defined above:

$$\begin{aligned} \text{L1OF signal: } & \Delta = 0; 10 \leq f_d \leq 20; \text{ and } 2 \leq \sigma \leq 8. \\ \text{L1OC signal: } & \Delta = 0; 0.1 \leq f_d \leq 14; \text{ and } 0.1 \leq \sigma \leq 24. \\ \text{L3OC signal: } & \Delta = 0; 0.1 \leq f_d \leq 8; \text{ and } 0.1 \leq \sigma \leq 15. \end{aligned}$$

Threat Model B for Galileo corresponding to second order anomalies uses the following ranges for the parameters defined above:

$$\begin{aligned} \text{E1-C signal: } & \Delta = 0; 0.1 \leq f_d \leq 18; \text{ and } 0.1 \leq \sigma \leq 63. \\ \text{E5a-Q signal: } & \Delta = 0; 0.1 \leq f_d \leq 8; \text{ and } 0.1 \leq \sigma \leq 23. \end{aligned}$$

Threat Model B for BDS corresponding to second order anomalies uses the following ranges for the parameters defined above:

$$\begin{aligned} \text{B1C_pilot signal: } & \Delta = 0; 1.5 \leq f_d \leq 18; \text{ and } 0.1 \leq \sigma \leq 20. \\ \text{B2a_pilot signal: } & \Delta = 0; 4 \leq f_d \leq 18; \text{ and } 0.1 \leq \sigma \leq 18. \end{aligned}$$

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

8.5.3 Within these parameter ranges, threat Model B generates distortions of the correlation peak as well as false peaks.

8.6 Threat Model C introduces both lead/lag and amplitude modulation. Specifically, it consists of outputs from a second order system when the C/A code signal at the input suffers from lead or lag. This waveform is a combination of the two effects described above.

8.6.1 Threat Model C for GPS includes parameters Δ , f_d and σ with the following ranges:

L1 signal: $-0.12 \mu\text{s} \leq \Delta \leq 0.12 \mu\text{s}$; $7.3 \leq f_d \leq 13$; and $0.8 \leq \sigma \leq 8.8$.

L5 signal: $-0.10 \mu\text{s} \leq \Delta \leq 0.10 \mu\text{s}$; $7.3 \leq f_d \leq 13$; and $0.8 \leq \sigma \leq 8.8$.

Threat Model C for GLONASS includes parameters Δ , f_d and σ with the following ranges:

L1OF signal: $-0.22 \mu\text{s} \leq \Delta \leq 0.22 \mu\text{s}$; $10 \leq f_d \leq 20$; and $2 \leq \sigma \leq 8$.

L1OC signal: $-0.1 \mu\text{s} \leq \Delta \leq 0.1 \mu\text{s}$; $0.1 \leq f_d \leq 14$; and $0.1 \leq \sigma \leq 24$.

L3OC signal: $-0.1 \mu\text{s} \leq \Delta \leq 0.1 \mu\text{s}$; $0.1 \leq f_d \leq 8$; and $0.1 \leq \sigma \leq 15$.

Threat Model C for Galileo includes parameters Δ , f_d and σ with the following ranges:

E1-C signal: $-0.12 \mu\text{s} \leq \Delta \leq 0.12 \mu\text{s}$; $0.1 \leq f_d \leq 18$; and $0.1 \leq \sigma \leq 63$.

E5a-Q signal: $-0.1 \mu\text{s} \leq \Delta \leq 0.1 \mu\text{s}$; $0.1 \leq f_d \leq 8$; and $0.1 \leq \sigma \leq 23$.

Threat Model C for BDS includes parameters Δ , f_d and σ with the following ranges:

B1C_pilot signal: $-0.05 \leq \Delta \leq 0.05$; $1.5 \leq f_d \leq 18$; and $0.1 \leq \sigma \leq 20$.

B2a_pilot signal: $-0.05 \leq \Delta \leq 0.05$; $4 \leq f_d \leq 18$; and $0.1 \leq \sigma \leq 18$.

8.6.2 Within these parameter ranges, threat Model C generates dead zones, distortions of the correlation peak and false peaks.

8.7 Unlike core constellation signals, the SBAS ranging signal is commissioned and controlled by the service provider. Moreover, the service provider also monitors the quality of the signal from the SBAS. To this end, the threat model will be specified and published by the service provider for each SBAS satellite. The SBAS SQM will be designed to protect all avionics that comply with Table D-12. Publication of the threat model is required for those cases where a service provider chooses to allow the SBAS L1 ranging signal from a neighbouring service provider to be used for precision approach by SBAS or GBAS. In these cases, the service provider will monitor the SBAS ranging signal from the neighbouring satellite.

8.8 In order to analyze the performance of a particular monitor design, the monitor limit must be defined and set to protect individual satellite pseudo-range error relative to the protection level, with an allocation of the ground subsystem integrity risk. The maximum tolerable error (denoted as MERR) for each ranging source i can be defined in GBAS, L1 SBAS and DFMC SBAS as:

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 142

$$MERR_{GBAS} = K_{ffmd} \sigma_{pr_gnd,i} \text{ and}$$

$$MERR_{L1 SBAS} = K_{V,PA} \sqrt{\sigma_{i,UDRE}^2 + \min\{\sigma_{i,UIRE}^2\}}$$

$$MERR_{DFMC SBAS} = K_{V,PA} \sqrt{\sigma_{i,DFRE}^2}$$

for SBAS, and in particular for L1 SBAS APV and precision approach where $\min\{\sigma_{i,UDRE}^2\}$ is the minimum possible value for any user, MERR is evaluated at the output of a fault-free user receiver and varies with satellite elevation angle and ground subsystem performance.

8.9 The SQM is designed to limit the worst differential error to values below the MERR in the case of a satellite anomaly. Typically, the SQM measures various correlation peak values and generates spacing and ratio metrics that characterize correlation peak distortion. Figure D-9 illustrates typical points at the top of a fault-free, unfiltered correlation peak.

8.9.1 A correlator pair is used for tracking. All other correlator values are measured with respect to this tracking pair.

8.9.2 Two types of test metrics are formed: early-minus-late metrics (D) that are indicative of tracking errors caused by peak distortion, and amplitude ratio metrics (R) that measure slope and are indicative of peak flatness or close-in, multiple peaks.

8.9.3 It is necessary that the SQM has a precorrelation bandwidth that is sufficiently wide to measure the narrow spacing metrics, so as not to cause significant peak distortion itself and not to mask the anomalies caused by the satellite failure. Typically, the SQM receiver must have a precorrelation bandwidth of at least 16 MHz for GPS L1 and at least 24 MHz for L5, at least 15 MHz for GLONASS, at least 24 MHz for Galileo and at least 24 MHz for BDS.

8.9.4 The test metrics are smoothed using low-pass digital filters. The time constant of these filters are to be shorter than those used jointly by the reference receivers for deriving differential corrections and by the aircraft receiver for smoothing pseudo-range measurements (and standardized at 100 seconds). The smooth metrics are then compared to thresholds. If any one of the thresholds is exceeded, an alarm is generated for that satellite.

8.9.5 The thresholds used to derive performance are defined as minimum detectable errors (MDEs) and minimum detectable ratios (MDRs). Fault-free false detection probability and missed detection probability are used to derive MDEs and MDRs. The noise in metrics (D) and (R), as denoted $\sigma_{D,test}$ and $\sigma_{R,test}$ below, is dominated by multipath errors. Note that the metric test can also have a mean value (μ_{test}) caused by SQM receiver filter distortion. Threshold tests must also account for the mean values.

8.9.6 The MDE and MDR values used in the SQM performance simulations are calculated based on the following equation

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 143

$$MDE = (K_{\text{ffd}} + K_{\text{md}}) \sigma_{D,\text{test}} \text{ and}$$

$$MDR = (K_{\text{ffd}} + K_{\text{md}}) \sigma_{R,\text{test}}$$

where

$K_{\text{ffd}} = 5.26$ is a typical fault-free detection multiplier representing a false detection probability of 1.5×10^{-7} per test. The false detection probability may be allocated to each metric used in the SQM depending on the number of metrics implemented;

8.9.7 If multiple independent SQM receivers are used to detect the failures, the sigma values can be reduced by the square root of the number of independent monitors.

8.9.8 A failure is declared if

$$| D_{,\text{test}} - \mu_{D,\text{test}} | \geq MDE \text{ or}$$

$$| R_{,\text{test}} - \mu_{R,\text{test}} | \geq MDR$$

for any of the tests performed, where $\mu_{X,\text{test}}$ is the mean value of the test X that accounts for fault-free SQM receiver filter distortion, as well as correlation peak distortion associated with the specific code. Code correlation peaks can have different slopes across different codes within the same code family. In a simulation environment, however, this code distortion can be ignored, and a perfect correlation peak can be used, except for simulated filter distortion.)

8.10 The standard deviations of the test statistics, $\sigma_{D,\text{test}}$ and $\sigma_{R,\text{test}}$ can be determined via data collection on a multicorrelator receiver in the expected operating environment. The data collection receiver utilizes a single tracking pair of correlators and additional correlation function measurement points which are slaved to this tracking pair, as illustrated in Figure D-18 for GPS and GLONASS and in Figure FIG-09 for Galileo and BDS. Data is collected and smoothed for all available measurement points in order to compute the metrics. The standard deviation of these metrics define $\sigma_{D,\text{test}}$. It is also possible to compute this one sigma test statistics if a multipath model of the installation environment is available.

8.10.1 The resulting $\sigma_{D,\text{test}}$ is highly dependent on the multipath environment in which the data are collected. The deviation due to multipath can be an order of magnitude greater than that which would result from noise even at minimum carrier-to-noise level. This aspect illustrates the importance of the antenna design and siting criteria which are the primary factors in determining the level of multipath that will enter the receiver. Reducing multipath will significantly decrease the resulting MDEs and thus improve the SQM capabilities.

8.10.2 Mean values $\mu_{D,\text{test}}$ and $\mu_{R,\text{test}}$, on the other hand, are determined in a relatively error-free environment, such as through the use of core constellation satellite signal simulator as input. These mean values model the nominal SQM receiver's filter distortion of the autocorrelation peak, including the effects of distortion due to adjacent minor autocorrelation peaks. The mean values can differ for the various PRNs based on these properties.

8.10.3 The presence of nominal signal deformation biases may cause the distribution of the monitor detectors to have non-zero mean. These biases can be observed by averaging measurements taken from a real-world data collection. Note that the nominal biases may depend on elevation and they typically change slowly over time. For example, nominal GPS deformations are leads and lags that are present in unfaulted conditions and thus may exist all the time. The nominal GPS deformation is in the range $-0.01\mu\text{s} \leq \Delta \leq 0.01\mu\text{s}$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 144

8.10.4 The SQM for SBAS is validated for the signal distortions defined by the GPS, GLONASS, Galileo and BDS TM-A/B/C threat space only for a vertical alert limit greater or equal to 35 m.

8.11 In order for the ground monitor to protect users against the different threat models described above, it is necessary to assume that aircraft receivers have specific characteristics. If no such constraints were assumed, the complexity of the ground monitor would be unnecessarily high. Evolution in the technology may lead to improved detection capability in the aircraft receiver and may alleviate the current constraints.

8.11.1 For double-delta correlators, the aircraft receiver tracks the strongest correlation peak over the full code sequence for every ranging source used in the navigation solution.

8.11.2 For double-delta correlators, the precorrelation filter rolls off by at least 30 dB per octave in the transition band. For GBAS receivers, the resulting attenuation in the stop band is required to be greater than or equal to 50 dB (relative to the peak gain in the pass band).

8.11.3 The following parameters are used to describe the tracking performance specific to each type of satellite:

- a) the instantaneous correlator spacing is defined as the spacing between a particular set of early and late samples of the correlation function;
- b) the average correlator spacing is defined as a one-second average of the instantaneous correlator spacing. The average applies over any one-second time frame;
- c) the discriminator is based upon an average of early-minus-late samples with spacings inside the specified range, or is of the type $= 2 d1 - 2d1$, with both $d1$ and $2d1$ in the specified range. Either a coherent or non-coherent discriminator is used;
- d) the differential group delay applies to the entire aircraft system prior to the correlator, including the antenna. The differential group delay is defined as:

$$\left| \frac{d\phi}{d\omega}(f_c) - \frac{d\phi}{d\omega}(f) \right|$$

where

f_c is the precorrelation band pass filter centre frequency;

f is any frequency within the 3dB bandwidth of the precorrelation filter;

ϕ is the combined phase response of precorrelation band pass filter and antenna; and

ω is equal to $2\pi f$.

8.11.4 For aircraft receivers supporting single-frequency L1 using early-late correlators and tracking GPS L1 C/A satellites signal, the precorrelation bandwidth of the installation, the correlator spacing and the differential group delay are within the ranges defined in Table D-11, except as noted below.

8.11.4.1 For GBAS airborne equipment using early-late correlators and tracking GPS satellites, the precorrelation bandwidth of the installation, the correlator spacing and the differential group delay (including

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 145

the contribution of the antenna) are within the ranges defined in Table D-11, except that the region 1 minimum bandwidth will increase to 4 MHz and the average correlator spacing is reduced to an average of 0.21 chips or instantaneous of 0.235 chips.

8.11.4.2 For GBAS airborne equipment class D (GAEC D) receivers using early-late correlators and tracking GPS satellites, the precorrelation bandwidth of the installation, the correlator spacing and the differential group delay are within the ranges defined in Table D-11, regions 2, 3 or 4 only. In addition, in region 2 the range of average correlator spacing is 0.045 – 0.12 chips, and the instantaneous correlator spacing is 0.04 – 0.15 chips.

8.11.4.3 For SBAS airborne equipment using early-late correlators and tracking GPS L1 C/A satellites signal, the precorrelation bandwidth of the installation, the correlator spacing and the differential group delay (including the contribution of the antenna) are within the ranges of the first three regions defined in Table D-11 for L1 signal.

8.11.5 For aircraft receivers supporting single-frequency L1 using early-late correlators and tracking GLONASS satellites, the precorrelation bandwidth of the installation, the correlator spacing, and the differential group delay are within the ranges as defined in Table D-12.

8.11.5.1 For GBAS airborne equipment class D (GAEC D) aircraft receivers using early-late correlators and tracking GLONASS satellites, the precorrelation bandwidth of the installation, the correlator spacing, and the differential group delay are within the ranges as defined in Table D-12, regions 2 and 3 only. In addition, in region 2 the range of average correlator spacing is 0.05 – 0.1 chips, and the instantaneous correlator spacing is 0.045 – 0.11 chips.

8.11.6 For aircraft receivers supporting single-frequency L1 using double-delta correlators and tracking GPS L1 C/A satellites signal, the precorrelation bandwidth of the installation, the correlator spacing and the differential group delay are within the ranges defined in Tables D-13A and D-13B.

8.11.6.1 For GBAS airborne equipment class D (GAEC D) receivers using double-delta correlators and tracking GPS satellites, the precorrelation bandwidth of the installation, the correlator spacing and the differential group delay are within the ranges defined in Table D-13, regions 2 and 3 only.

8.11.7 For aircraft receivers supporting single-frequency L1 and using the early-late or double-delta correlators and tracking SBAS L1 satellites, the precorrelation bandwidth of the installation, the correlator spacing and the differential group delay are within the ranges defined in Table D-14.

8.11.7.1 For GBAS airborne equipment class D (GAEC D) receivers using the early-late or double-delta correlators and tracking SBAS satellites, the precorrelation bandwidth of the installation, the correlator spacing and the differential group delay are within the ranges defined in Table D-14, region 2 only. In addition, for GAEC D receivers using early-late correlators and tracking SBAS satellites, the average correlator spacing is 0.045 – 0.12 chips, and the instantaneous correlator spacing is 0.04 – 0.15 chips.

8.11.8 For aircraft receivers designed for DFMC SBAS, the L5 (or L3) signal tracking precorrelation bandwidth of the installation, the correlator spacing and the differential group delay are within the ranges defined in Table TAB-09 using the early-late correlators and tracking the GPS, Galileo, GLONASS, BDS or SBAS L5 signals identified in Attachment B, section 3.5.11.1.

8.11.9 For aircraft receivers designed for DFMC SBAS, the L1 signal tracking precorrelation bandwidth of the installation, the correlator spacing and the differential group delay are within the ranges defined in Table TAB-10 using the early-late correlators and tracking the GPS, Galileo, GLONASS, BDS or SBAS L1 signals identified in Attachment B, section 3.5.11.1.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

8.11.10 The instantaneous correlator spacing may be larger than the average correlator spacing range provided in Table TAB-09 and Table TAB-10 accounting for noise or jitter in the correlator spacing.

9. Status Monitoring and Notam

9.1 System status

9.1.1 Degradation of GBAS usually has local effects and affects mainly approach operations. System degradation of GBAS is to be distributed as approach-related information.

9.1.2 Degradation of core satellite constellation(s) or SBAS can be limited to local effects affecting mainly approach operations, but can also impact a wider area, and may directly affect en-route operations in the SBAS service area(s). System degradation impacting en-route or wider area SBAS operations is to be distributed as area-related information. An example is an ionosphere storm that removes all vertically-guided approach capability. System degradation impacting limited approaches can be distributed as approach-related information.

9.1.3 Degradation of GRAS may have local effects and/or wide area effects. Therefore, if the degradation has only local effects, GRAS system degradation information is to be distributed in accordance with 9.1.1. If the degradation has wide area effects, GRAS system degradation information is to be distributed in accordance with 9.1.2.

9.1.4 Information is to be distributed to indicate the inability of GNSS to support a defined operation. For example, GPS/SBAS may not support a precision approach operation on a particular approach. This information can be generated automatically or manually based upon models of system performance.

Table D-22. GPS tracking constraints for early-late correlators

<i>Region</i>	<i>3 dB precorrelation bandwidth, BW</i>	<i>Average correlator spacing (chips)</i>	<i>Instantaneous correlator spacing (chips)</i>	<i>Differential group delay</i>
1	$2 < BW \leq 7$ MHz	0.045 – 1.1	0.04 – 1.2	≤ 600 ns

9.2 Information on type of degradation

The following information is to be distributed:

- a) non-availability of service;
- b) downgrade of service, if applicable; and
- c) time and expected duration of degradation.

9.3 Timing of notification

For scheduled events, notification should be given to the NOTAM authority at least 72 hours prior to the event. For unscheduled events, notification to the NOTAM authority should be given within 15 minutes. Notification should be given for events of 15-minute, or longer, duration.

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 149

10. Inteference

10.1 Potential for interference

Satellite radio navigation systems such as GPS ~~and~~ GLONASS, Galileo and BDS feature relatively weak received signal power, meaning that an interference signal could cause loss of service. In order to maintain service, it will be necessary to ensure that the maximum interference levels specified in the SARPs are not exceeded.

10.2 In-band interference sources

A potential source of in-band harmful interference is Fixed Service operation in certain States. There is a primary allocation to the fixed service for point-to-point microwave links in certain States in the frequency band used by GPS, GLONASS, Galileo and BDS.

10.3 Out-of-band interference sources

Potential sources of out-of-band interference include harmonics and spurious emissions of aeronautical VHF and UHF transmitters. Out-of-band noise, discrete spurious products and intermodulation products from radio and TV broadcasts can also cause interference problems.

10.4 Aircraft generated sources

10.4.1 The potential for harmful interference to GPS, GLONASS, Galileo and BDS on an aircraft depends on the type of aircraft, its size and the transmitting equipment installed. The GNSS antenna location should take into account the possibility of on-board interference (mainly SATCOM).

10.4.2 GNSS receivers that are used on board aircraft with SATCOM equipment must have a higher interference threshold in the frequency range between 1 610 MHz and 1 626.5 MHz than receivers on board aircraft without SATCOM equipment. Therefore, specifications for the interference threshold discriminate between both cases.

Note. — Limits for radiated SATCOM aircraft earth stations are given in BCAR -10, Volume III, Part I, Chapter 4, 4.2.3.5.

10.4.3 The principal mitigation techniques for on-board interference include shielding, filtering, receiver design techniques, and, especially on larger aircraft, physical separation of antennas, transmitters and cabling. Receiver design techniques include the use of adaptive filters and interference cancellation techniques that mitigate against narrow in-band interference. Antenna design techniques include adaptive null steering antennas that reduce the antenna gain in the direction of interference sources without reducing the signal power from satellites.

10.5 Integrity in the presence of interference

The requirement that GNSS receivers do not output misleading information in the presence of interference is intended to prevent the output of misleading information under unintentional interference scenarios that could arise. It is not intended to specifically address intentional interference. While it is impossible to completely verify this requirement through testing, an acceptable means of compliance can be found in the appropriate receiver Minimum Operational Performance Standards published by RTCA and EUROCAE.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 150

11. Recording of GNSS Parameter

11.1 In order to be able to conduct post-incident/accident investigations (Chapter 2, 2.1.4.2 and 2.1.4.3), it is necessary to record GNSS information both for the augmentation system and for the appropriate GNSS core system constellation used for the operation. The parameters to be recorded are dependent on the type of operation, augmentation system and core elements used. All parameters available to users within a given service area should be recorded at representative locations in the service area.

11.2 The objective is not to provide independent assurance that the GNSS is functioning correctly, nor is it to provide another level of system monitoring for anomalous performance or input data for a NOTAM process. The recording system need not be independent of the GNSS service and may be delegated to other States or entities. In order to enable future reconstruction of position, velocity and time indications provided by specific GNSS configurations, it is recommended to log data continuously, generally at a 1 Hz rate.

11.3 For GNSS core systems the following monitored items should be recorded for all satellites in view:

- a) observed satellite carrier-to-noise density (C/N_0);
- b) observed satellite raw pseudo-range code and carrier phase measurements;
- c) broadcast satellite navigation messages, for all satellites in view; and
- d) relevant recording receiver status information.

11.4 For SBAS the following monitored items should be recorded for all SBAS satellites in view in addition to the GNSS core system monitored items listed above:

- a) observed SBAS satellite carrier-to-noise density (C/N_0);
- b) observed SBAS satellite raw pseudo-range code and carrier phase measurements;
- c) broadcast SBAS data messages; and
- d) relevant receiver status information.

11.5 For GBAS the following monitored items should be recorded in addition to the GNSS core system and SBAS monitored items listed above (where appropriate):

- a) VDB power level;
- b) VDB status information; and
- c) broadcast GBAS data messages.

12. GNSS Performance Assessment

12.1 GNSS performance assessment is a periodic offline activity that can be performed by ANSP or delegated to other entity, aiming to verify that GNSS performance parameters conform to the relevant BCAR 10 Standards. This activity can be done for the core constellation, the augmentation system or a combination of both.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 151

Note.— Additional guidance material on GNSS performance assessment is provided in the Global Navigation Satellite System (GNSS) Manual (Doc 9849).

The data described in Section 11 may also support periodic confirmation of GNSS performance in the service area.

13. GNSS and Database

Note - Provisions relating to aeronautical data are contained in BCAR 11, Chapter 2, and BCAR 15, Chapter 3.

13.1 The database is to be current with respect to the effective AIRAC cycle, which generally means that a current database be loaded into the system approximately every 28 days. Operating with out-of-date navigation databases has to be avoided.

13.2 In certain situations, operations using an expired database can be conducted safely by implementing a process and/or using procedures to ensure that the required data is correct. These processes and/or procedures need prior approval by theBCAA.

13.2.1 These procedures should be based on one of the following methods:

- a) require the crew to check, prior to the operation, critical database information against current published information. (This method increases workload and would not be practical for all applications.); or
- b) waive the requirement for a current database and frequent checks by the crew of the database information. This waiver can only be applied to very specific cases where aircraft are operated in a strictly limited geographical area and where that area is controlled by a single regulatory agency or multiple agencies that coordinate this process; or
- c) use another approved method that ensures an equivalent level of safety.

14. Modeling OF Residual Errors

14.1 Application of the integrity requirements for SBAS and GBAS requires that a model distribution be used to characterize the error characteristics in the pseudo-range. The HPL/LPL and VPL models (see 7.5.3) are constructed based on models of the individual error components (in the pseudo-range domain) that are independent, zero-mean, normal distributions. The relationship between this model and the true error distribution must be defined.

14.2 One method of ensuring that the protection level risk requirements are met is to define the model variance (σ^2), such that the cumulative error distribution satisfies the conditions:

$$\int_y^{\infty} f(x)dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \left(\frac{y}{\sigma}\right) \geq 0 \text{ and}$$

$$\int_{-\infty}^{-y} f(x)dx \leq Q\left(\frac{y}{\sigma}\right) \text{ for all } \left(\frac{y}{\sigma}\right) \geq 0 \text{ and}$$

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Information and guidance in the application of the standard and recommended practices	Attachment D	Page: 152

where

$f(x)$ = probability density function of the residual aircraft pseudo-range error component; and

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} e^{-\frac{t^2}{2}} dt.$$

14.3 This method can be directly applied when the error components have zero-mean, symmetrical and unimodal probability density functions. This is the case for the receiver contribution to corrected pseudo-range error, since

14.4 This method can be extended to address non-zero-mean, residual errors by inflating the model variance to compensate for the possible effect of the mean in the position domain.

14.5 Verification of the pseudo-range error models must consider a number of factors including:

- a) the nature of the error components;
- b) the sample size required for confidence in the data collection and estimation of each distribution;
- c) the correlation time of the errors; and
- d) the sensitivity of each distribution to geographic location and time.

	Guidance material on the pre-flight checking of VOR airborne equipment	Attachment E	Page: 1

ATTACHEMENT-E GUIDANCE MATERIAL ON THE PRE FLIGHT-CHECKING OF VOR AIRBORNE EQUIPMENT

1. Specification for a VOR airborne equipment test facility (VOT)

1.1 Introduction

For the guidance of ANSP wishing to provide a test signal for the pre-flight checking of VOR airborne equipment, suggested characteristics for a VOR airborne equipment test facility (VOT) are given hereafter.

1.2 General

1.2.1 The VOT must be designed to provide signals that will permit satisfactory operation of a typical VOR aircraft installation in those areas of the aerodrome where pre-flight checking is convenient and desirable.

1.2.2 The VOT must be constructed and adjusted so that the VOR bearing indicator in the aircraft will indicate zero degrees “FROM” when the receiver has not departed from calibration. This indication remains constant irrespective of the aircraft's angular position with respect to the VOT within the intended coverage.

1.2.3 In view of the manner in which use is made of a VOT, there is no fundamental need for its duplication at any one site.

1.2.4 The VOT is required to radiate a radio frequency carrier with which are associated two separate 30 Hz modulations. The characteristics of these modulations should be identical with the reference phase and variable phase signals associated with VOR. The phases of these modulations should be independent of azimuth and should be coincident with each other at all times.

1.3 Radio frequency

The VOT should operate in the band 108 to 117.975 MHz on an appropriate VOR channel selected so as not to interfere with any VHF navigation or communication services. The highest assignable frequency is 117.95 MHz. The frequency tolerance of the radio frequency carrier should be plus or minus 0.005 per cent, except as specified in Chapter 3, 3.3.2.2 and 3.3.2.3.

1.4 Polarization and accuracy

1.4.1 The emission from the VOT should be horizontally polarized.

1.4.2 The accuracy of the “bearing” information conveyed by the radiation from the VOT should be plus or minus 1 degree.

Note - Since the two modulations on the radio frequency carrier are in phase coincidence at all times, the vestigial vertically polarized energy will have no effect on the accuracy of the facility.

1.5 Coverage

1.5.1 Coverage requirements, and hence the power which must be radiated, will necessarily depend to a considerable extent on local circumstances. For some installations, a small fraction of 1 W will suffice while in other cases, particularly if two or more closely adjacent aerodromes are to be served by a single test facility, several watts of radio frequency energy may need to be emitted.

1.5.2 Where there is a need to protect co-channel VORs, VOTs and ILS localizers from VOT interference, the radio emission must be limited to that required to provide satisfactory operation and to ensure that interference with other co-channel assignments does not occur.

1.6 Modulation

1.6.1 The radio frequency carrier as observed at any point in space should be amplitude modulated by two signals as follows:

- a) a subcarrier of 9 960 Hz of constant amplitude, frequency modulated at 30 Hz and having a deviation ratio of 16 plus or minus 1 (i.e. 15 to 17);
- b) 30 Hz.

1.6.2 The depth of modulation due to the 9 960 Hz and the 30 Hz signals should be within the limits of 28 per cent for each component.

1.6.3 The signal which frequency modulates the 9 960 Hz subcarrier and the signal which amplitude modulates the radio frequency carrier should both be maintained at 30 Hz within plus or minus 1 per cent.

1.6.4 The frequency of the 9 960 Hz subcarrier should be maintained within plus or minus 1 per cent.

1.6.5 The percentage of amplitude modulation on the 9 960 Hz subcarrier present at the output of the transmitter should not be greater than 5 per cent.

1.7 Identification

1.7.1 The VOT should transmit a 1 020 Hz identification signal. The identification code for a VOT installation should be selected by the competent authority so as to be unmistakably distinctive as to the test function and, if necessary, as to the location.

Note - In one State, when the VOT coverage is confined to a single aerodrome, the identification consists of a continuous series of dots.

1.7.2 The depth to which the radio frequency carrier is modulated by the identification signal should be approximately 10 per cent.

1.8 Monitoring

1.8.1 Basically, there is no need for continuous automatic monitoring of VOT provided the relative phase of the AM and FM 30 Hz components are mechanically locked and facilities exist for periodic inspection and remote supervision of the state of the VOT.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Guidance material on the pre-flight checking of VOR airborne equipment	Attachment E	Page: 3

1.8.2 Provision of automatic monitoring can double the cost of a VOT installation and, consequently, many competent authorities are likely to employ only remote supervision at a control point. However, where, in the light of the operational use to be made of a VOT, a ANSP decides to provide automatic monitoring, the monitor should transmit a warning to a control point and cause a cessation of transmission if either of the following deviations from established conditions arises:

- a) a change in excess of 1 degree at the monitor site of the “bearing” information transmitted by the VOT;
- b) a reduction of 50 per cent in the signal level of the 9 960 Hz or 30 Hz signals at the monitor.

Failure of the monitor should automatically cause a cessation of transmission.

2. Selection and use of VOR aerodrome check-points

2.1 General

2.1.1 When a VOR is suitably located in relationship to an aerodrome, the pre-flight checking of an aircraft VOR installation can be facilitated by the provision of suitably calibrated and marked check-points at convenient parts of the aerodrome.

2.1.2 In view of the wide variation in circumstances encountered, it is not practicable to establish any standard requirements or practices for the selection of VOR aerodrome check-points. However, ANSPs wishing to provide this facility should be guided by the following considerations in selecting the points to be used.

2.2 Siting requirements for check-points

2.2.1 The signal strength of the nearby VOR has to be sufficient to ensure satisfactory operation of a typical aircraft VOR installation. In particular, full flag action (no flag showing) must be ensured.

2.2.2 The check-points should, within the limits of operating convenience, be located away from buildings or other reflecting objects (fixed or moving) which are likely to degrade the accuracy or stability of the VOR signal.

2.2.3 The observed VOR bearing at any selected point should ideally be within plus or minus 1.5 degrees of the bearing accurately determined by survey or chart plotting.

Note - The figure of plus or minus 1.5 degrees has no direct operational significance in that the observed bearing becomes the published bearing; however, where a larger difference is observed, there is some possibility of poor stability.

2.2.4 The VOR information at a selected point should be used operationally only if found to be consistently within plus or minus 2 degrees of the published bearing. The stability of the VOR information at a selected point should be checked periodically with a calibrated receiver to ensure that the plus or minus 2-degree tolerance is satisfied, irrespective of the orientation of the VOR receiving antenna.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Guidance material on the pre-flight checking of VOR airborne equipment	Attachment E	Page: 4

Note - The tolerance of plus or minus 2 degrees relates to the consistency of the information at the selected point and includes a small tolerance for the accuracy of the calibrated VOR receiver used in checking the point. The 2-degree figure does not relate to any figure for acceptance or rejection of an aircraft VOR installation, this being a matter for determination by Administrations and users in the light of the operation to be performed.

2.2.5 Check-points which can satisfy the foregoing requirements should be selected in consultation with the operators concerned. Provision of check-points in holding bays, at runway ends and in maintenance and loading areas, is usually desirable.

2.3 Marking of VOR check-points

Each VOR check-point must be distinctively marked. This marking must include the VOR bearing which a pilot would observe on the aircraft instrument if the VOR installation were operating correctly.

2.4 Use of VOR check-points

The accuracy with which a pilot must position the aircraft with respect to a check-point will depend on the distance from the VOR station. In cases where the VOR is relatively close to a check-point, particular care must be taken to place the aircraft's VOR receiving antenna directly over the check-point.

ATTACHMENT F. GUIDANCE MATERIAL CONCERNING RELIABILITY AND AVAILABILITY OF RADIOCOMMUNICATIONS AND NAVIGATION AIDS

1. Introduction and fundamental concepts

This Attachment is intended to provide guidance material which ANSP may find helpful in providing the degree of facility reliability and availability consistent with their operational requirement.

The material in this Attachment is intended for guidance and clarification purposes, and is not to be considered as part of the Standards and Recommended Practices contained in this BCAR.

1.1 Definitions

Facility availability. The ratio of actual operating time to specified operating time.

Facility failure. Any unanticipated occurrence which gives rise to an operationally significant period during which a facility does not provide service within the specified tolerances.

Facility reliability. The probability that the ground installation operates within the specified tolerances.

Note.— This definition refers to the probability that the facility will operate for a specified period of time.

Mean time between failures (MTBF). The actual operating time of a facility divided by the total number of failures of the facility during that period of time.

Note.— The operating time is in general chosen so as to include at least five, and preferably more, facility failures in order to give a reasonable measure of confidence in the figure derived.

Signal reliability. The probability that a signal-in-space of specified characteristics is available to the aircraft.

Note - This definition refers to the probability that the signal is present for a specified period of time.

1.2 Facility reliability

1.2.1 Reliability is achieved by a combination of factors. These factors are variable and may be individually adjusted for an integrated approach that is optimum for, and consistent with, the needs and conditions of a particular environment. For example, one may compensate to some extent for low reliability by providing increased maintenance staffing and/or equipment redundancy. Similarly, low levels of skill among maintenance personnel may be offset by providing equipment of high reliability.

1.2.2 The following formula expresses facility reliability as a percentage:

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Guidance material on communication and navigation aids	Attachment F	Page: 2

$$R = 100 e^{-t/m}$$

where:

R = reliability (probability that the facility will be operative within the specified tolerances for a time t , also referred to as probability of survival, P_s);

e = base of natural logarithms;

t = time period of interest;

m = mean time between facility failures.

It may be seen that reliability increases as mean time between failures (MTBF) increases. For a high degree of reliability, and for operationally significant values of t , we must have a large MTBF; thus, MTBF is another more convenient way of expressing reliability.

1.2.3 Experimental evidence indicates that the above formula is true for the majority of electronic equipments where the failures follow a Poisson distribution. It will not be applicable during the early life of an equipment when there is a relatively large number of premature failures of individual components; neither will it be true when the equipment is nearing the end of its useful life.

1.2.4 At many facility types utilizing conventional equipment, MTBF values of 1 000 hours or more have been consistently achieved. To indicate the significance of a 1 000-hour MTBF, the corresponding 24-hour reliability is approximately 97.5 per cent (i.e. the likelihood of facility failure during a 24-hour period is about 2.5 per cent).

1.2.5 Figure F-1 shows the probability of facility survival, P_s , after a time period, t , for various values of MTBF.

Note - It is significant that the probability of surviving a period of time equal to the MTBF is only 0.37 (37 per cent); thus, it is not assumed that the MTBF is a failure-free period.

1.2.6 It may be seen that adjustment of MTBF will produce the desired degree of reliability. Factors which affect MTBF and hence facility reliability are:

- a) inherent equipment reliability;
- b) degree and type of redundancy;
- c) reliability of the serving utilities such as power and telephone or control lines;
- d) degree and quality of maintenance;
- e) environmental factors such as temperature and humidity.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

1.3 Facility availability

1.3.1 Availability, as a percentage, may be expressed in terms of the ratio of actual operating time divided by specified operating time taken over a long period. Symbolically,

$$A = \frac{\text{Actual time operating (100)}}{\text{Specified operating time}}$$

Figure F-1. Plot of $P_s = 100 e^{-t/m}$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Guidance material on communication and navigation aids	Attachment F	Page: 4

For example, if a facility was operating normally for a total of 700 hours during a 720-hour month, the availability for that month would be 97.2 per cent.

1.3.2 Factors important in providing a high degree of facility availability are:

- a) facility reliability;
- b) quick response of maintenance personnel to failures;
- c) adequate training of maintenance personnel;
- d) equipment designs providing good component accessibility and maintainability;
- e) efficient logistic support;
- f) provision of adequate test equipment;
- g) standby equipment and/or utilities.

2. Practical aspects of reliability and availability

2.1 Measurement of reliability and availability

2.1.1 Reliability. The value that is obtained for MTBF in practice must of necessity be an estimate since the measurement will have to be made over a finite period of time. Measurement of MTBF over finite periods of time will enable Administrations to determine variations in the reliability of their facilities.

2.1.2 Availability. This is also important in that it provides an indication of the degree to which a facility (or group of facilities) is available to the users. Availability is directly related to the efficiency achieved in restoring facilities to normal service.

2.1.3 The basic quantities and manner of their measurement are indicated in Figure F-2. This figure is not intended to represent a typical situation which would normally involve a larger number of inoperative periods during the specified operating time. It should also be recognized that to obtain the most meaningful values for reliability and availability the specified operating time over which measurements are made should be as long as practicable.

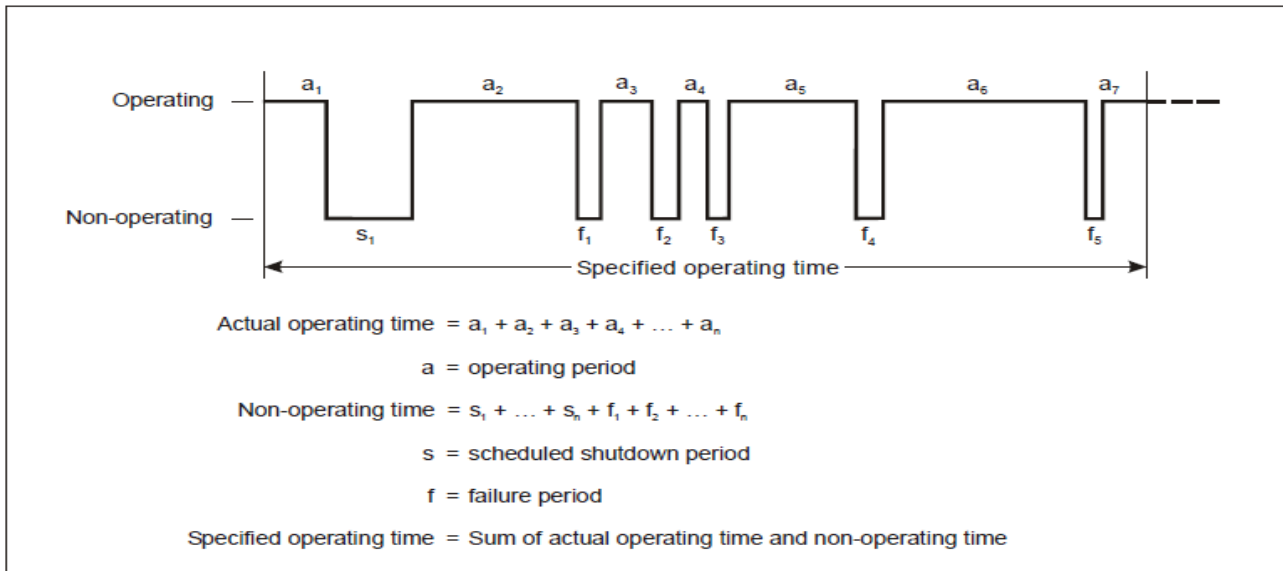

Figure F-2. Evaluation of facility availability and reliability

2.1.4 Using the quantities illustrated in Figure F-2, which includes one scheduled shutdown period and five failure periods, one may calculate mean time between failures (MTBF) and availability (A) as follows:

Let:

$$\begin{aligned}
 a_1 + a_2 + a_3 + a_4 + a_5 + a_6 + a_7 &= 5\,540 \text{ hours} \\
 s_1 &= 20 \text{ hours} \\
 f_1 &= 2\frac{1}{2} \text{ hours} \\
 f_2 &= 6\frac{3}{4} \text{ hours} \\
 f_3 &= 3\frac{3}{4} \text{ hours} \\
 f_4 &= 5 \text{ hours} \\
 f_5 &= 2\frac{1}{2} \text{ hours}
 \end{aligned}$$

$$\text{Specified operating time} = 5\,580 \text{ hours}$$

$$\begin{aligned}
 \text{MTBF} &= \frac{\text{Actual operating time}}{\text{Number of failures}} \\
 &= \frac{\sum_{i=1}^7 a_i}{5} \\
 &= \frac{5\,540}{5} = 1\,108 \text{ hours}
 \end{aligned}$$

	Aeronautical telecommunication Volume - I	BCAR-10	
	Guidance material on communication and navigation aids	Attachment F	Page: 6

$$\begin{aligned}
 A &= \frac{\text{Actual operating time} \times 100}{\text{Specified operating time}} \\
 &= \frac{\sum_{i=1}^7 a_i \times 100}{\sum_{i=1}^7 a_i + s_1 + \sum_{i=1}^5 f_i} \\
 &= \frac{5\,540}{5\,580} \times 100 = 99.3 \text{ per cent}
 \end{aligned}$$

	Rationalization of conventional radio navigation aids and evolution toward supporting PBN	Attachment G	Page: 1

ATTACHMENT H. STRATEGY FOR RATIONALIZATION OF CONVENTIONAL RADIO NAVIGATION AIDS AND EVOLUTION TOWARD SUPPORTING PERFORMANCE-BASED NAVIGATION (see Chapter 2, 2.1)

1. Introduction

1.1 The shift from facility-referenced navigation to coordinate-based navigation enabled by performance-based navigation (PBN) provides significant benefits, in particular by supplying the flexibility required to design airspace and associated routes and procedures according to operational needs. The most suitable navigation infrastructure to support PBN is GNSS. Consequently, the role of conventional navigation aids is currently evolving towards that of a reversionary terrestrial infrastructure capable of maintaining safety and an adequate level of operations in case of unavailability of GNSS (for example due to outages). During this evolution, terrestrial aids may also enable PBN operations for users not yet equipped with GNSS.

1.2 The aim of the strategy set out in this attachment is to provide guidance to ANSPs to enable both a rationalization of navigation aids as well as a coordinated evolution towards the provision of a reversionary terrestrial infrastructure. This strategy should be considered in particular when deciding on investments into new facilities or on facility renewals. The context of this evolution of navigation infrastructure is described in the *Global Air Navigation Plan* (ICAO Doc 9750).

1.3 The strategy addresses the application of radio navigation aids to both conventional and performance-based navigation in en-route and terminal airspace, as well as their use as non-precision approach aids. Detailed guidance on PBN navigation infrastructure requirements is available in the *Performance-based Navigation (PBN) Manual* (ICAO Doc 9613).

Note - The strategy relating to approach and landing with vertical guidance (APV) and precision approach and landing operations is contained in Attachment B.

2.Objectives of the strategy

The strategy must:

- a) maintain at least the current safety level of en-route and terminal area navigation operations;
- b) facilitate the implementation of performance-based navigation (PBN);
- c) maintain global interoperability;
- d) provide regional flexibility based on coordinated regional planning;
- e) encourage airspace users to equip with appropriate PBN avionics; and
- f) take account of economic, operational and technical issues.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Rationalization of conventional radio navigation aids and evolution toward supporting PBN	Attachment G	Page: 2

3. Considerations

3.1 Operational considerations

The following considerations are based on the assumption that the operational requirements are defined, that the required resources are committed, and that the required effort is applied. In particular, changes in radio navigation facility provision require associated efforts in airspace planning, procedure design, consideration of regulatory aspects and broad consultation with impacted airspace users.

3.2 NDB-related considerations

3.2.1 NDBs serve no role in PBN operations except as a means for position cross-checking and general situational awareness. These minor roles should not lead to the requirement to retain NDB facilities.

3.2.2 Except where no other alternative is available due to constraints in user fleet, financial, terrain or safety limitations:

- a) the use of NDBs as en-route navigation aids or terminal area markers is generally obsolete;
- b) NDBs used to support SID/STAR should be replaced by RNAV waypoints;
- c) NDBs used as locators to assist in ILS intercept operations should be replaced by RNAV waypoints;
- d) the use of NDB to support missed approach operations should be discouraged except where local safety cases require a non-GNSS missed approach capability; and
- e) NDBs used as a non-precision approach aid should be withdrawn, taking the opportunity offered by the implementation of Assembly Resolution 37-11.

3.3 VOR related considerations

3.3.1 The only PBN navigation specification enabled by VOR, provided a co-located DME is present, is RNAV 5. Provision of RNAV 5 based on VOR/DME is subject to significant limitations, since integrated multi-sensor navigation makes very little use of VOR/DME, in some cases limiting the range of use to 25 NM. Also, only very few aircraft operators have a certified RNAV 5 capability which is based only on VOR/DME. Consequently, the use of VOR/DME to provide PBN services is discouraged. The only exception to this could be to support RNAV 5 routes at or near the bottom of en-route airspace (above minimum sector altitude, MSA) where achieving DME/DME coverage is challenging.

3.3.2 In principle, to enable cost savings, VOR facilities should be withdrawn in the context of an overall PBN plan. No new stand-alone VOR facilities (e.g. at new locations) should be implemented. However, VORs may be retained to serve the following residual operational purposes:

- a) as a reversionary navigation capability (for example, for general aviation operations in order to assist in avoiding airspace infringements);

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Rationalization of conventional radio navigation aids and evolution toward supporting PBN	Attachment G	Page: 3

- b) to provide navigation, cross-checking and situational awareness, especially for terminal area operations (pilot MSA awareness, avoiding premature automatic flight control system arming for ILS intercept, aircraft operational contingency procedures, such as engine failure on take-off, missed approaches, if required by local safety cases), in particular in areas where low altitude DME/DME coverage is limited;
- c) for VOR/DME inertial updating where DME/DME updating is not available;
- d) for non-precision approaches, as long as users are not equipped for RNP approaches and if no other suitable means of precision approach is available;
- e) for conventional SID/STAR to serve non-PBN-capable aircraft;
- f) as required to support the operations of State aircraft; and
- g) to support procedural separation (as detailed in ICAO Doc 4444).

3.3.3 In order to provide DME-based RNAV capabilities, those locations which are retained for VOR should normally also be equipped with a co-located DME.

3.3.4 It is expected that adherence to the above principles should enable a decrease of the current number of facilities by 50 per cent or more in areas which support high densities of traffic. To achieve such results, ANSPs should develop a rationalization plan, taking into account the service age, all uses and operational roles of their facilities. This normally requires significant coordination with airspace users. The rationalization plan should be an integral part of the PBN implementation plan. Experience has shown that the associated project effort amounts to less expense than the replacement and refurbishment of a single VOR facility. The rationalization planning for VOR is also an important input into the evolution planning for DME.

3.4 DME-related considerations

3.4.1 DME/DME fully supports PBN operations based on the RNAV 1, RNAV 2 and RNAV 5 navigation specifications. Consequently, DME/DME (for equipped aircraft) is the most suitable current terrestrial PBN capability. DME/DME provides a fully redundant capability to GNSS for RNAV applications, and a suitable reversionary capability for RNP applications requiring an accuracy performance of ± 1 NM (95 per cent) laterally, where supported by an adequate DME infrastructure.

Note - While some aircraft are certified to provide RNP based on DME/DME, the ability of DME to provide RNP on a general basis is currently under investigation.

3.4.2 ANSPs are encouraged to plan the evolution of their DME infrastructure by considering the following:

- a) Where a terrestrial navigation reversion capability is required, a DME network capable of supporting DME/DME navigation should be provided, where possible;
- b) the DME network design should consider cost-savings opportunities whenever possible, such as the withdrawal from a site if an associated VOR is removed, or the possibility to efficiently set up new DME stand-alone sites where other ANSP CNS assets are located;

	Aeronautical telecommunication Volume - I	BCAR-10	
	Rationalization of conventional radio navigation aids and evolution toward supporting PBN	Attachment G	Page: 4

- c) the DME network design should attempt to fill any gaps and provide coverage to as low altitudes as operationally useful without leading to excessive new facilities investments;
- d) if satisfactory DME/DME coverage cannot be achieved, ANSPs may consider requiring INS equipage from airspace users to bridge gaps in coverage;
- e) ANSPs should take maximum advantage of cross-border and military facilities (TACAN), provided the necessary agreements can be put in place; and
- f) the frequency assignment of new DME stations should avoid the GNSS L5/E5 band (1 164 – 1 215 MHz) in areas of high DME station density, if possible.

3.4.3 If the above principles are adhered to, it is expected that the density of DME stations in a given area should become more uniform. In other words, the number of facilities in areas of high station density will be reduced, whereas it may need to be increased in areas of low station density.

3.4.4 It is recognized that in some areas, the provision of DME/DME navigation is not possible or practical, such as at very low altitudes, in terrain-constrained environments, or on small islands and areas over water. It should also be noted that some FMS exclude the use of ILS-associated DMEs. As a consequence, it is not possible to ensure consistent DME/DME service to all DME/DME-equipped users based on ILS-associated DMEs, and thus those facilities cannot be used to provide such service (regardless of whether they are published in the en-route section of the AIP).

3.5 Multi-sensor airborne navigation capability considerations

It is recognized that:

- a) until all airspace users are both equipped and approved with suitable GNSS-based PBN capabilities, terrestrial navigation aids must be provided either to support conventional procedures or to support DME/DME-based PBN capabilities;
- b) once all airspace users are both equipped and approved with suitable GNSS-based PBN capabilities, terrestrial navigation aids may need to be provided to mitigate the risks associated with GNSS outages;
- c) it may not be practical or cost-efficient for some airspace users to equip with DME/DME-based and/or INS-based PBN capabilities; and
- d) a review of flight plan filings can be an efficient tool to analyse user fleet equipage status; however, actual equipage and approval status may need to be confirmed by the aircraft operator.

Third Edition	Revision 00	Bhutan Civil Aviation Authority	April 2024
---------------	-------------	---------------------------------	------------

	Aeronautical telecommunication Volume - I	BCAR-10	
	Rationalization of conventional radio navigation aids and evolution toward supporting PBN	Attachment G	Page: 5

3.6 Other considerations

3.6.1 The evolution of terrestrial navigation infrastructure must be accompanied by the development of corresponding operational reversion scenarios. Operational requirements must be balanced with regard to that which is possible at a reasonable cost, while ensuring safety. In particular, coverage requirements at low altitude can be associated with significant facility cost. Leveraging airspace user capabilities, such as INS, as well as other CNS capabilities (surveillance and communication service coverage and associated ATC capabilities) must be considered to the maximum extent practicable, including common mode failures. In some airspaces, it may not be possible to cater to all airspace user equipage levels and, as a consequence, some airspace users may become subject to operational restrictions.

3.6.2 Reserved

3.6.3 It must be noted that the use of the term “network” in this strategy refers only to navigation facilities assessed on a regional scale, and it does not refer to a network of routes or a particular airspace design. In high-density airspace, it is considered impractical to provide an alternate, conventional back-up route network, once the transition to a fully PBN-based route network has been achieved.

3.6.4 In a few limited cases, it may not be possible to provide the same level of benefits through the application of PBN as is possible when using conventional navigation capabilities, due to procedure design limitations or other aspects such as terrain-constrained environments. ANSPs are invited to bring these cases to the attention of BCAA.

4.Strategy

Based on the considerations above, the need to consult aircraft operators and international organizations, and to ensure safety, efficiency and cost-effectiveness of the proposed solutions, the global strategy is to:

- a) rationalize NDB and VOR and associated procedures;
- b) align rationalization planning with equipment life cycles and PBN implementation planning;
- c) replace approaches without vertical guidance with vertically guided approaches;
- d) where a terrestrial navigation reversion capability is required, evolve the existing DME infrastructure towards providing a PBN infrastructure complementary to GNSS;
- e) provide a residual capability based on VOR (or VOR/DME, if possible) to cater to airspace users not equipped with suitable DME/DME avionics, where required; and
- f) enable each region to develop an implementation strategy for these systems in line with the global strategy.
